

## ADM690–ADM695

### FEATURES

Superior Upgrade for MAX690–MAX695  
 Specified Over Temperature  
 Low Power Consumption (5 mW)  
 Precision Voltage Monitor  
 Reset Assertion Down to 1 V  $V_{CC}$   
 Low Switch On-Resistance 1.5  $\Omega$  Normal,  
 20  $\Omega$  in Backup  
 High Current Drive (100 mA)  
 Watchdog Timer—100 ms, 1.6 s, or Adjustable  
 600 nA Standby Current  
 Automatic Battery Backup Power Switching  
 Extremely Fast Gating of Chip Enable Signals (5 ns)  
 Voltage Monitor for Power Fail

### APPLICATIONS

Microprocessor Systems  
 Computers  
 Controllers  
 Intelligent Instruments  
 Automotive Systems

### GENERAL DESCRIPTION

The ADM690–ADM695 family of supervisory circuits offers complete single chip solutions for power supply monitoring and battery control functions in microprocessor systems. These functions include  $\mu$ P reset, backup battery switchover, watchdog timer, CMOS RAM write protection, and power failure warning. The complete family provides a variety of configurations to satisfy most microprocessor system requirements.

The ADM690, ADM692 and ADM694 are available in 8-pin DIP packages and provide:

1. Power-on reset output during power-up, power-down and brownout conditions. The  $\overline{\text{RESET}}$  output remains operational with  $V_{CC}$  as low as 1 V.
2. Battery backup switching for CMOS RAM, CMOS microprocessor or other low power logic.
3. A reset pulse if the optional watchdog timer has not been toggled within a specified time.
4. A 1.3 V threshold detector for power fail warning, low battery detection, or to monitor a power supply other than +5 V.

The ADM691, ADM693 and ADM695 are available in 16-pin DIP and small outline packages and provide three additional functions.

1. Write protection of CMOS RAM or EEPROM.
2. Adjustable reset and watchdog timeout periods.
3. Separate watchdog timeout, backup battery switchover, and low  $V_{CC}$  status outputs.

### REV. A

Information furnished by Analog Devices is believed to be accurate and reliable. However, no responsibility is assumed by Analog Devices for its use, nor for any infringements of patents or other rights of third parties which may result from its use. No license is granted by implication or otherwise under any patent or patent rights of Analog Devices.

### FUNCTIONAL BLOCK DIAGRAMS

<sup>1</sup>VOLTAGE DETECTOR = 4.65V (ADM690, ADM694)  
 4.40V (ADM692)

<sup>2</sup>RESET PULSE WIDTH = 50ms (ADM690, ADM692)  
 200ms (ADM694)

<sup>1</sup>VOLTAGE DETECTOR = 4.65V (ADM691, ADM695)  
 4.40V (ADM693)

The ADM690–ADM695 family is fabricated using an advanced epitaxial CMOS process combining low power consumption (5 mW), extremely fast Chip Enable gating (5 ns) and high reliability. RESET assertion is guaranteed with  $V_{CC}$  as low as 1 V. In addition, the power switching circuitry is designed for minimal voltage drop thereby permitting increased output current drive of up to 100 mA without the need for an external pass transistor.

# ADM690–ADM695–SPECIFICATIONS

( $V_{CC}$  = Full Operating Range,  $V_{BATT} = +2.8\text{ V}$ ,  $T_A = T_{MIN}$  to  $T_{MAX}$  unless otherwise noted)

\*Stresses above those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum ratings for extended periods of time may affect device reliability.

**CAUTION**

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the ADM690–ADM695 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## PIN FUNCTION DESCRIPTION

Mnemonic	Function
$V_{CC}$	Power Supply Input: +5 V Nominal.
$V_{BATT}$	Backup Battery Input. Connect to Ground if a backup battery is not used.
$V_{OUT}$	Output Voltage, $V_{CC}$ or $V_{BATT}$ is internally switched to $V_{OUT}$ depending on which is at the highest potential. $V_{OUT}$ can supply up to 100 mA to power CMOS RAM. Connect $V_{OUT}$ to $V_{CC}$ if $V_{OUT}$ and $V_{BATT}$ are not used.
GND	0 V. Ground reference for all signals.
$\overline{RESET}$	<p>Logic Output. <math>\overline{RESET}</math> goes low if</p> <ol style="list-style-type: none"> <li><math>V_{CC}</math> falls below the Reset Threshold</li> <li><math>V_{CC}</math> falls below <math>V_{BATT}</math></li> <li>The watchdog timer is not serviced within its timeout period.</li> </ol> <p>The reset threshold is typically 4.65 V for the ADM690/ADM691/ADM694/ADM695 and 4.4 V for the ADM692 and ADM693. <math>\overline{RESET}</math> remains low for 50 ms (ADM690/ADM691/ADM692/ADM693) or 200 ms (ADM694/ADM695) after <math>V_{CC}</math> returns above the threshold. <math>\overline{RESET}</math> also goes low for 50 (200) ms if the watchdog timer is enabled but not serviced within its timeout period. The <math>\overline{RESET}</math> pulse width can be adjusted on the ADM691/ADM693/ADM695 as shown in Table I. The <math>\overline{RESET}</math> output has an internal 3 <math>\mu</math>A pull up, and can either connect to an open collector Reset bus or directly drive a CMOS gate without an external pull-up resistor.</p>
WDI	Watchdog Input. WDI is a three level input. If WDI remains either high or low for longer than the watchdog timeout period, $\overline{RESET}$ pulses low and WDO goes low. The timer resets with each transition on the WDI line. The watchdog timer may be disabled if WDI is left floating or is driven to midsupply.
PFI	Power Fail Input. PFI is the noninverting input to the Power Fail Comparator when PFI is less than 1.3 V, $\overline{PFO}$ goes low. Connect PFI to GND or $V_{OUT}$ when not used.
$\overline{PFO}$	Power Fail Output. $\overline{PFO}$ is the output of the Power Fail Comparator. It goes low when PFI is less than 1.3 V. The comparator is turned off and $\overline{PFO}$ goes low when $V_{CC}$ is below $V_{BATT}$ .
$\overline{CE}_{IN}$	Logic Input. The input to the $\overline{CE}$ gating circuit. Connect to GND or $V_{OUT}$ if not used.
$\overline{CE}_{OUT}$	Logic Output. $\overline{CE}_{OUT}$ is a gated version of the $\overline{CE}_{IN}$ signal. $\overline{CE}_{OUT}$ tracks $\overline{CE}_{IN}$ when $V_{CC}$ is above the reset threshold. If $V_{CC}$ is below the reset threshold, $\overline{CE}_{OUT}$ is forced high. See Figures 5 and 6.
BATT ON	Logic Output. BATT ON goes high when $V_{OUT}$ is internally switched to the $V_{BATT}$ input. It goes low when $V_{OUT}$ is internally switched to $V_{CC}$ . The output typically sinks 35 mA and can directly drive the base of an external PNP transistor to increase the output current above the 100 mA rating of $V_{OUT}$ .
$\overline{LOW LINE}$	Logic Output. $\overline{LOW LINE}$ goes low when $V_{CC}$ falls below the reset threshold. It returns high as soon as $V_{CC}$ rises above the reset threshold.
RESET	Logic Output. RESET is an active high output. It is the inverse of $\overline{RESET}$ .
OSC SEL	Logic Oscillator Select Input. When OSC SEL is unconnected (floating) or driven high, the internal oscillator sets the reset active time and watchdog timeout period. When OSC SEL is low, the external oscillator input, OSC IN, is enabled. OSC SEL has a 3 $\mu$ A internal pull up, (see Table I).
OSC IN	Oscillator Logic Input. With OSC SEL low, OSC IN can be driven by an external clock signal or an external capacitor can be connected between OSC IN and GND. This sets both the reset active pulse timing and the watchdog timeout period (see Table I and Figure 4). With OSC SEL high or floating, the internal oscillator is enabled and the reset active time is fixed at 50 ms typ. (ADM691/ADM693) or 200 ms typ (ADM695). In this mode the OSC IN pin selects between fast (100 ms) and slow (1.6 s) watchdog timeout periods. In both modes, the timeout period immediately after a reset is 1.6 s typical.
$\overline{WDO}$	Logic Output. The Watchdog Output, $\overline{WDO}$ , goes low if WDI remains either high or low for longer than the watchdog timeout period. $\overline{WDO}$ is set high by the next transition at WDI. If WDI is unconnected or at midsupply, the watchdog timer is disabled and $\overline{WDO}$ remains high. $\overline{WDO}$ also goes high when $\overline{LOW LINE}$ goes low.

## PIN CONFIGURATIONS

## PRODUCT SELECTION GUIDE

Part Number	Nominal Reset Time	Nominal $V_{CC}$ Reset Threshold	Nominal Watchdog Timeout Period	Battery Backup Switching	Base Drive Ext PNP	Chip Enable Signals
ADM690	50 ms	4.65 V	1.6 s	Yes	No	No
ADM691	50 ms or ADJ	4.65 V	100 ms, 1.6 s, ADJ	Yes	Yes	Yes
ADM692	50 ms	4.4 V	1.6 s	Yes	No	No
ADM693	50 ms or ADJ	4.4 V	100 ms, 1.6 s, ADJ	Yes	Yes	Yes
ADM694	200 ms	4.65 V	1.6 s	Yes	No	No
ADM695	200 ms or ADJ	4.65 V	100 ms, 1.6 s, ADJ	Yes	Yes	Yes

### CIRCUIT INFORMATION

#### Battery Switchover Section

The battery switchover circuit compares  $V_{CC}$  to the  $V_{BATT}$  input, and connects  $V_{OUT}$  to whichever is higher. Switchover occurs when  $V_{CC}$  is 50 mV higher than  $V_{BATT}$  as  $V_{CC}$  falls, and when  $V_{CC}$  is 70 mV greater than  $V_{BATT}$  as  $V_{CC}$  rises. This 20 mV of hysteresis prevents repeated rapid switching if  $V_{CC}$  falls very slowly or remains nearly equal to the battery voltage.

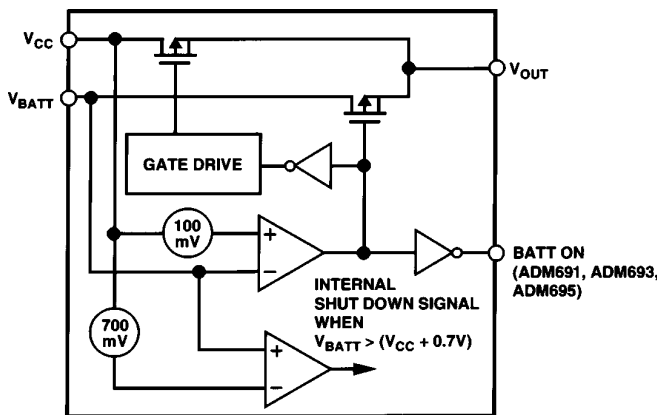

Figure 1. Battery Switchover Schematic

During normal operation with  $V_{CC}$  higher than  $V_{BATT}$ ,  $V_{CC}$  is internally switched to  $V_{OUT}$  via an internal PMOS transistor switch. This switch has a typical on-resistance of 1.5  $\Omega$  and can supply up to 100 mA at the  $V_{OUT}$  terminal.  $V_{OUT}$  is normally used to drive a RAM memory bank which may require instantaneous currents of greater than 100 mA. If this is the case then a bypass capacitor should be connected to  $V_{OUT}$ . The capacitor will provide the peak current transients to the RAM. A capacitance value of 0.1  $\mu\text{F}$  or greater may be used.

If the continuous output current requirement at  $V_{OUT}$  exceeds 100 mA or if a lower  $V_{CC}$ - $V_{OUT}$  voltage differential is desired, an external PNP pass transistor may be connected in parallel with the internal transistor. The BATT ON output (ADM691/ADM693/ADM695) can directly drive the base of the external transistor.

A 20  $\Omega$  MOSFET switch connects the  $V_{BATT}$  input to  $V_{OUT}$  during battery backup. This MOSFET has very low input-to-output differential (dropout voltage) at the low current levels required for battery back up of CMOS RAM or other low power CMOS circuitry. The supply current in battery back up is typically 0.6  $\mu\text{A}$ .

The ADM690/ADM691/ADM694/ADM695 operates with battery voltages from 2.0 V to 4.25 V and the ADM692/ADM693 operates with battery voltages from 2.0 V to 4.0 V. High value capacitors, either standard electrolytic or the farad size double layer capacitors, can also be used for short-term memory back up. A small charging current of typically 10 nA (0.1  $\mu\text{A}$  max) flows out of the  $V_{BATT}$  terminal. This current is useful for maintaining rechargeable batteries in a fully charged condition. This extends the life of the back up battery by compensating for its self discharge current. Also note that this current poses no problem when lithium batteries are used for back up since the maximum charging current (0.1  $\mu\text{A}$ ) is safe for even the smallest lithium cells.

If the battery-switchover section is not used,  $V_{BATT}$  should be connected to GND and  $V_{OUT}$  should be connected to  $V_{CC}$ .

# ADM690–ADM695

## POWER FAIL RESET OUTPUT

$\overline{\text{RESET}}$  is an active low output which provides a  $\overline{\text{RESET}}$  signal to the Microprocessor whenever  $V_{\text{CC}}$  is at an invalid level. When  $V_{\text{CC}}$  falls below the reset threshold, the  $\overline{\text{RESET}}$  output is forced low. The nominal reset voltage threshold is 4.65 V (ADM690/ADM691/ADM694/ADM695) or 4.4 V (ADM692/ADM693).

Figure 2. Power Fail Reset Timing

On power-up  $\overline{\text{RESET}}$  will remain low for 50 ms (200 ms for ADM694 and ADM695) after  $V_{\text{CC}}$  rises above the appropriate reset threshold. This allows time for the power supply and microprocessor to stabilize. On power-down, the  $\overline{\text{RESET}}$  output remains low with  $V_{\text{CC}}$  as low as 1 V. This ensures that the microprocessor is held in a stable shutdown condition.

This  $\overline{\text{RESET}}$  active time is adjustable on the ADM691/ADM693/ADM695 by using an external oscillator or by connecting an external capacitor to the OSC IN pin. Refer to Table I and Figure 4.

The guaranteed minimum and maximum thresholds of the ADM690/ADM691/ADM694/ADM695 are 4.5 V and 4.73 V, while the guaranteed thresholds of the ADM692/ADM693 are 4.25 V and 4.48 V. The ADM690/ADM691/ADM694/ADM695 is, therefore, compatible with 5 V supplies with a +10%, -5% tolerance while the ADM692/ADM693 is compatible with 5 V  $\pm$  10% supplies. The reset threshold comparator has approximately 50 mV of hysteresis. The response time of the reset voltage comparator is less than 1  $\mu\text{s}$ . If glitches are present on the  $V_{\text{CC}}$  line which could cause spurious reset pulses, then  $V_{\text{CC}}$  should be decoupled close to the device.

In addition to  $\overline{\text{RESET}}$  the ADM691/ADM693/ADM695 contain an active high  $\overline{\text{RESET}}$  output. This is the complement of  $\overline{\text{RESET}}$  and is intended for processors requiring an active high RESET signal.

## Watchdog Timer RESET

The watchdog timer circuit monitors the activity of the microprocessor in order to check that it is not stalled in an indefinite loop. An output line on the processor is used to toggle the Watchdog Input (WDI) line. If this line is not toggled within the selected timeout period, a  $\overline{\text{RESET}}$  pulse is generated. The nominal watchdog timeout period is preset at 1.6 seconds on the ADM690/ADM692/ADM694. The ADM691/ADM693/ADM695 may be configured for either a fixed “short” 100 ms or a “long” 1.6 second timeout period or for an adjustable timeout period. If the “short” period is selected, some systems may be unable to service the watchdog timer immediately after a reset, so the ADM691/ADM693/ADM695 automatically selects the “long” timeout period directly after a reset is issued. The watchdog timer is restarted at the end of reset, whether the reset was caused by lack of activity on WDI or by  $V_{\text{CC}}$  falling below the reset threshold.

The normal (short) timeout period becomes effective following the first transition of WDI after  $\overline{\text{RESET}}$  has gone inactive. The watchdog timeout period restarts with each transition on the WDI pin. To ensure that the watchdog timer does not time out, either a high-to-low or low-to-high transition on the WDI pin must occur at or less than the minimum timeout period. If WDI remains permanently either high or low, reset pulses will be issued after each “long” timeout period (1.6 s). The watchdog monitor can be deactivated by floating the Watchdog Input (WDI) or by connecting it to midsupply.

Figure 3. Watchdog Timeout Period and Reset Active Time

**Table I. ADM691, ADM693, ADM695 Reset Pulse Width and Watchdog Timeout Selections**

OSC SEL	OSC IN	Watchdog Timeout Period		Reset Active Period	
		Normal	Immediately After Reset	ADM691/ADM693	ADM695
Low	External Clock Input	1024 CLKS	4096 CLKS	512 CLKS	2048 CLKS
Low	External Capacitor	$260 \text{ ms} \times C/47 \text{ pF}$	$1.04 \text{ s} \times C/47 \text{ pF}$	$130 \text{ ms} \times C/47 \text{ pF}$	$520 \text{ ms} \times C/47 \text{ pF}$
Floating or High	Low	100 ms	1.6 s	50 ms	200 ms
Floating or High	Floating or High	1.6 s	1.6 s	50 ms	200 ms

**NOTE**

With the OSC SEL pin low, OSC IN can be driven by an external clock signal, or an external capacitor can be connected between OSC IN and GND. The nominal internal oscillator frequency is 10.24 kHz. The nominal oscillator frequency with external capacitor is:  $F_{\text{OSC}} \text{ (Hz)} = 184,000/C \text{ (pF)}$ .

The watchdog timeout period is fixed at 1.6 seconds, and the reset pulse width is fixed at 50 ms on the ADM690/ADM692. On the ADM694 the watchdog timeout period is also 1.6 seconds but the reset pulse width is fixed at 200 ms. The ADM691/ADM693/ADM695 allow these times to be adjusted as shown in Table I. Figure 4 shows the various oscillator configurations which can be used to adjust the reset pulse width and watchdog timeout period.

The internal oscillator is enabled when OSC SEL is high or floating. In this mode, OSC IN selects between the 1.6 second and 100 ms watchdog timeout periods. With OSC IN connected high or floating, the 1.6 second timeout period is selected; while with it connected low, the 100 ms timeout period is selected. In either case, immediately after a reset, the timeout period is 1.6 seconds. This gives the microprocessor time to reinitialize the system. If OSC IN is low, then the 100 ms watchdog period becomes effective after the first transition of WDI. The software should be written such that the I/O port driving WDI is left in its power-up reset state until the initialization routines are completed and the microprocessor is able to toggle WDI at the minimum watchdog timeout period of 70 ms.

**Watchdog Output (WDO)**

The Watchdog Output  $\overline{\text{WDO}}$  (ADM691/ADM693/ADM695) provides a status output which goes low if the watchdog timer “times out” and remains low until set high by the next transition on the Watchdog Input.  $\overline{\text{WDO}}$  is also set high when  $V_{\text{CC}}$  goes below the reset threshold.

## CE Gating and RAM Write Protection (ADM691/ADM693/ADM695)

The ADM691/ADM693/ADM695 products include memory protection circuitry which ensures the integrity of data in memory by preventing write operations when  $V_{CC}$  is at an invalid level. There are two additional pins,  $\overline{CE}_{IN}$  and  $\overline{CE}_{OUT}$ , which may be used to control the Chip Enable or Write inputs of CMOS RAM. When  $V_{CC}$  is present,  $\overline{CE}_{OUT}$  is a buffered replica of  $\overline{CE}_{IN}$ , with a 5 ns propagation delay. When  $V_{CC}$  falls below the reset voltage threshold or  $V_{BATT}$ , an internal gate forces  $\overline{CE}_{OUT}$  high, independent of  $\overline{CE}_{IN}$ .

$\overline{CE}_{OUT}$  typically drives the  $\overline{CE}$ ,  $\overline{CS}$ , or write input of battery backed up CMOS RAM. This ensures the integrity of the data in memory by preventing write operations when  $V_{CC}$  is at an invalid level. Similar protection of EEPROMs can be achieved by using the  $\overline{CE}_{OUT}$  to drive the store or write inputs.

If the 5 ns typical propagation delay of  $\overline{CE}_{OUT}$  is excessive, connect  $\overline{CE}_{IN}$  to GND and use the resulting  $\overline{CE}_{OUT}$  to control a high speed external logic gate.

## Power Fail Warning Comparator

An additional comparator is provided for early warning of failure in the microprocessor's power supply. The Power Fail Input (PFI) is compared to an internal +1.3 V reference. The Power Fail Output (PFO) goes low when the voltage at PFI is less than 1.3 V. Typically PFI is driven by an external voltage divider which senses either the unregulated dc input to the system's 5 V regulator or the regulated 5 V output. The voltage divider ratio can be chosen such that the voltage at PFI falls below 1.3 V several milliseconds before the +5 V power supply falls below the reset threshold.  $\overline{PFO}$  is normally used to interrupt the microprocessor so that data can be stored in RAM and the shut down procedure executed before power is lost

Figure 7. Power Fail Comparator

Table II. Input and Output Status In Battery Backup Mode

Signal	Status
$V_{OUT}$	$V_{OUT}$ is connected to $V_{BATT}$ via an internal PMOS switch.
$\overline{RESET}$	Logic low.
RESET	Logic high. The open circuit output voltage is equal to $V_{OUT}$ .
$\overline{LOW LINE}$	Logic low.
BATT ON	Logic high. The open circuit voltage is equal to $V_{OUT}$ .
WDI	WDI is ignored. It is internally disconnected from the internal pull-up resistor and does not source or sink current as long as its input voltage is between GND and $V_{OUT}$ . The input voltage does not affect supply current.
$\overline{WDO}$	Logic high. The open circuit voltage is equal to $V_{OUT}$ .
PFI	The Power Fail Comparator is turned off and has no effect on the Power Fail Output.
$\overline{PFO}$	Logic low.
$\overline{CE}_{IN}$	$\overline{CE}_{IN}$ is ignored. It is internally disconnected from its internal pull-up and does not source or sink current as long as its input voltage is between GND and $V_{OUT}$ . The input voltage does not affect supply current.
$\overline{CE}_{OUT}$	Logic high. The open circuit voltage is equal to $V_{OUT}$ .
OSC IN	OSC IN is ignored.
OSC SEL	OSC SEL is ignored.

## +APPLICATION INFORMATION

### Increasing the Drive Current

If the continuous output current requirements at  $V_{OUT}$  exceed 100 mA or if a lower  $V_{CC}-V_{OUT}$  voltage differential is desired, an external PNP pass transistor may be connected in parallel with the internal transistor. The BATT ON output (ADM691/ADM693/ADM695) can directly drive the base of the external transistor.

Figure 17. Increasing the Drive Current

### Using a Rechargeable Battery for Back Up

If a capacitor or a rechargeable battery is used for back up then the charging resistor should be connected to  $V_{OUT}$  since this eliminates the discharge path that would exist during power down if the resistor is connected to  $V_{CC}$ .

Figure 18. Rechargeable Battery

### Adding Hysteresis to the Power Fail Comparator

For increased noise immunity, hysteresis may be added to the power fail comparator. Since the comparator circuit is non-inverting, hysteresis can be added simply by connecting a resistor between the PFO output and the PFI input as shown in Figure 19.

When  $\overline{PFO}$  is low, resistor  $R_3$  sinks current from the summing junction at the PFI pin. When  $\overline{PFO}$  is high, the series combination of  $R_3$  and  $R_4$  source current into the PFI summing junction. This results in differing trip levels for the comparator.

$$V_H = 1.3V \left( 1 + \frac{R_1}{R_2} + \frac{R_1}{R_3} \right)$$

$$V_L = 1.3V \left( 1 + \frac{R_1}{R_2} - \frac{R_1(5V - 1.3V)}{1.3V(R_3 + R_4)} \right)$$

ASSUMING  $R_4 \ll R_3$  THEN  
HYSTERESIS  $V_H - V_L = 5V \left( \frac{R_1}{R_2} \right)$

Figure 19. Adding Hysteresis to the Power Fail Comparator

### Monitoring the Status of the Battery

The power fail comparator can be used to monitor the status of the backup battery instead of the power supply if desired. This is shown in Figure 20. The PFI input samples the battery voltage and generates an active low PFO signal when the battery voltage drops below a chosen threshold. It may be necessary to apply a test load in order to determine the loaded battery voltage. This can be done under processor control using  $\overline{CE}_{OUT}$ . Since  $\overline{CE}_{OUT}$  is forced high during the battery backup mode, the test load will not be applied to the battery while it is in use, even if the microprocessor is not powered.

Figure 20. Monitoring the Battery Status

### Alternate Watchdog Input Drive Circuits

The watchdog feature can be enabled and disabled under program control by driving WDI with a 3-state buffer (Figure 21a). When three-stated, the WDI input will float thereby disabling the watchdog timer.

Figure 21a. Programming the Watchdog Input

This circuit is not entirely foolproof, and it is possible that a software fault could erroneously 3-state the buffer. This would then prevent the ADM69x from detecting that the microprocessor is no longer operating correctly. In most cases a better method is to extend the watchdog period rather than disabling the watchdog. This may be done under program control using the circuit shown in Figure 21b. When the control input is high, the OSC SEL pin is low and the watchdog timeout is set by the external capacitor. A 0.01 μF capacitor sets a watchdog timeout delay of 100 seconds. When the control input is low, the OSC SEL pin is driven high, selecting the internal oscillator. The 100 ms or the 1.6 s period is chosen, depending on which diode in Figure 21b is used. With D1 inserted the internal timeout is set at 100 ms, while with D2 inserted the timeout is set at 1.6 s.

Figure 21b. Programming the Watchdog Input

### Replacing the Backup Battery

When changing the backup battery with system power on, spurious resets can occur when the battery is removed. This occurs because the leakage current flowing out of the V<sub>BATT</sub> pin will charge up the stray capacitance. If the voltage on V<sub>BATT</sub> reaches within 50 mV of V<sub>CC</sub>, a reset pulse is generated.

If spurious resets during battery replacement are acceptable, then no action is required. If not, then one of the following solutions should be considered:

1. A capacitor from V<sub>BATT</sub> to GND. This gives time while the capacitor is charging up to replace the battery. The leakage current will charge up the external capacitor towards the V<sub>CC</sub> level. The time taken is related to the charging current, the size of external capacitor and the voltage differential between the capacitor and the charging voltage supply.

$$t = C_{EXT} \times V_{DIFF} / I$$

The maximum leakage (charging) current is 1 μA over temperature and  $V_{DIFF} = V_{CC} - V_{BATT}$ . Therefore, the capacitor size should be chosen such that sufficient time is available to make the battery replacement.

$$C_{EXT} = T_{REQD} (1 \mu A / (V_{CC} - V_{BATT}))$$

If a replacement time of 5 seconds is allowed and assuming a V<sub>CC</sub> of 4.5 V and a V<sub>BATT</sub> of 3 V

$$C_{EXT} = 3.33 \mu F$$

Figure 22a. Preventing Spurious RESETS During Battery Replacement

2. A resistor from V<sub>BATT</sub> to GND. This will prevent the voltage on V<sub>BATT</sub> from rising to within 50 mV of V<sub>CC</sub> during battery replacement.
