

STLC3055

WLL & ISDN-TA SUBSCRIBER LINE INTERFACE CIRCUIT

- MONOCHIP SLIC OPTIMISED FOR WLL & ISDN-TA APPLICATIONS
- IMPLEMENT ALL KEY FEATURES OF THE BORSHT FUNCTION
- SINGLE SUPPLY (5.5 TO 15.8V)
- BUILT IN DC/DC CONVERTER CONTROLLER.
- SOFT BATTERY REVERSAL WITH PROGRAMMABLE TRANSITION TIME.
- ON-HOOK TRANSMISSION.
- PROGRAMMABLE OFF-HOOK DETECTOR THRESHOLD
- METERING PULSE GENERATION AND FILTER
- INTEGRATED RINGING
- INTEGRATED RING TRIP
- PARALLEL CONTROL INTERFACE (3.3V LOGIC LEVEL)
- PROGRAMMABLE CONSTANT CURRENT FEED
- SURFACE MOUNT PACKAGE
- INTEGRATED THERMAL PROTECTION
- -40 TO +85°C OPERATING RANGE

ORDERING NUMBERS: STLC3055Q
STLC3055QTR

DESCRIPTION

The STLC3055 is a SLIC device specifically designed for WLL (Wireless Local Loop) and ISDN-Terminal Adaptors. One of the distinctive characteristics of this device is the ability to operate with a single supply voltage (from +5.5V to +15.8V) and self-generate the negative battery by means of an on-chip DC/DC converter controller that drives an external MOS switch.

The battery level is properly adjusted depending on the operating mode. A useful characteristic for

DESCRIPTION (continued)

these applications is the integrated ringing generator.

The control interface is a parallel type with open drain output and 3.3V logic levels.

The metering pulses are generated on chip starting from two logic signals (0, 3.3V) one define the metering pulse frequency and the other the metering pulse duration. An on chip circuit then provides the proper shaping and filtering. Metering pulse amplitude and shaping (rising and decay time) can be programmed by external components. A dedicated cancellation circuit avoid pos-

sible CODEC input saturation due to Metering pulse echo.

Constant current feed can be set from 20mA to 40mA. Off-hook detection threshold is programmable from 5mA to 9mA.

The device, developed in BCD100II technology (100V process), operates in the extended temperature range and integrates a thermal protection that sets the device in power down when T_j exceeds 140°C.

PIN CONNECTION**ABSOLUTE MAXIMUM RATINGS**

Symbol	Parameter	Value	Unit
V_{pos}	Positive Supply Voltage	-0.4 to +17	V
A/BGND	AGND to BGND	-1 to +1	V
V_{dig}	Pin D0, D1, D2, $\overline{\text{DET}}$, CKTTX	-0.4 to 5.5	V
T_j	Max. junction Temperature	150	°C
$V_{\text{btot}}^{(1)}$	$V_{\text{btot}} = V_{\text{pos}} + V_{\text{bat}} $. (Total voltage applied to the device supply pins).	100	V

(1) V_{bat} is self generated by the on chip DC/DC converter and can be programmed via RF1 and RF2.
RF1 and RF2 shall be selected in order to fulfil the a.m limits (see External Components Table page 10)

OPERATING RANGE

Symbol	Parameter	Value	Unit
V _{pos}	Positive Supply Voltage	5.5 to +15.8	V
A/BGND	AGND to BGND	-100 to +100	V
V _{dig}	Pin D0, D1, D2, $\overline{\text{DET}}$, CKTTX, PD	-0.25 to 5.25	V

PIN DESCRIPTION

N.	Name	Function
25	VPOS	Positive supply input ranging from 5.5V to 15.8V.
34	BGND	Battery Ground, must be shorted with AGND.
27	AGND	Analog Ground, must be shorted with BGND.
16	ZAC	AC impedance synthesis.
15	ZAC1	RX buffer output, the AC impedance is connected from this node to ZAC.
17	RS	Protection resistors image (the image resistor is connected from this node to ZAC).
18	ZB	Balance Network for 2 to 4 wire conversion (the balance impedance ZB is connected from this node to AGND. ZA impedance is connected from this node to ZAC1).
20	TX	4 wire output port (TX output). The signal is referred to AGND. If connected to single supply CODEC input it must be DC decoupled with proper capacitor.
14	RX	4 wire input port (RX input); 300K Ω input impedance. This signal is referred to AGND. If connected to single supply CODEC output it must be DC decoupled with proper capacitor.
19	CAC	AC feedback input, AC/DC split capacitor (CAC).
32	ILTF	Transversal line current image output.
41	TIP	2 wire port; TIP wire (I _a is the current sourced from this pin).
37	RING	2 wire port; RING wire (I _b is the current sunk into this pin).
28	RLIM	Constant current feed programming pin (via RLIM). RLIM should be connected close to this pin and PCB layout should avoid noise injection on this pin.
30	RTH	Off-hook threshold programming pin (via RTH). RTH should be connected close to this pin and PCB layout should avoid noise injection on this pin.
29	IREF	Internal bias current setting pin. RREF should be connected close to this pin and PCB layout should avoid noise injection on this pin.
43	CREV	Reverse polarity transition time control. One proper capacitor connected between this pin and AGND is setting the reverse polarity transition time. This is the same transition time used to shape the "trapezoidal ringing" during ringing injection.
31	RD	DC feedback and ring trip input. RD should be connected close to this pin and PCB layout should avoid noise injection on this pin.

PIN DESCRIPTION (continued)

N.	Name	Function
4	PD	Power Down input. Normally connected to CVCC (or to logic level high). Can be used to set TIP and Ring terminals in open circuit setting PD=0 and D0=D1=0.
26	CVCC	Internal positive voltage supply filter.
35	VBAT	Regulated battery voltage self generated by the device via DC/DC converter. Must be shorted to VBAT1.
23	GATE	Driver for external Power MOS transistor.
21	VF	Feedback input for DC/DC converter controller.
22	CLK	Power Switch Controller Clock (typ. 125KHz). From version marked STLC3055 A5, this pin can also be connected to CVCC or AGND. When the CLK pin is connected to CVCC an internal auto-oscillation is internally generated and it is used instead of the external clock. When the CLK pin is connected to AGND, the GATE output is disabled.
24	RSENSE	Voltage input for current sensing. RSENSE should be connected close to this pin and VPOS pin. The PCB layout should minimize the extra resistance introduced by the copper tracks.
1	D0	Control Interface: input bit 0.
2	D1	Control Interface: input bit 1.
3	D2	Control interface: input bit 2.
8	$\overline{\text{DET}}$	Logic interface output of the supervision detector (active low).
33	CSVR	Battery supply filter capacitor.
12	RTTX	Metering pulse cancellation buffer output. TTX filter network should be connected to this point. If not used should be left open.
13	FTTX	Metering pulse buffer input this signal is sent to the line and used to perform TTX filtering.
10	CTTX1	Metering burst shaping external capacitor.
11	CTTX2	Metering burst shaping external capacitor.
9	CKTTX	Metering pulse clock input (12 KHz or 16KHz square wave).
44	VBAT1	Frame connection. Must be shorted to VBAT.
5	RES	Reserved, must be connected to AGND.
6, 7, 36, 38, 39, 40, 42	NC	Not connected.

FUNCTIONAL DESCRIPTION

The STLC3055 is a device specifically developed for WLL and ISDN-TA applications.

It is based on a SLIC core, on purpose optimised for these applications, with the addition of a DC/DC converter controller to fulfil the WLL and ISDN-TA design requirements.

The SLIC performs the standard feeding, signalling and transmission functions.

It can be set in three different operating modes via the D0, D1, D2 pins of the control logic interface (0 to 3.3V logic levels). The loop status is carried out on the $\overline{\text{DET}}$ pin (active low).

The $\overline{\text{DET}}$ pin is an open drain output to allow easy interfacing with both 3.3V and 5V logic levels.

The four possible SLIC's operating modes are:

- Power Down

- High Impedance Feeding (HI-Z)
- Active
- Ringing

Table 1 shows how to set the different SLIC operating modes.

Table 1. SLIC operating modes.

PD	D0	D1	D2	Operating Mode
0	0	0	X	Power Down
1	0	0	X	H.I. Feeding (HI-Z)
1	0	1	0	Active Normal Polarity
1	0	1	1	Active Reverse Polarity
1	1	1	0	Active TTX injection (N.P.)
1	1	1	1	Active TTX injection (R.P.)
1	1	0	0/1	Ring (D2 bit toggles @ fring)

The DC/DC converter controller is driving an external power MOS transistor (P-Channel) in order to generate the negative battery voltage needed for device operation.

The DC/DC converter controller is synchronised with an external CLK (125KHZ typ.).

From version marked STLC3055 A5, it can be synchronised to an internal clock generated when the pin CLK is connected to CVCC. One sensing resistor in series to Vpos supply allows to fix the maximum allowed input peak current. This feature is implemented in order to avoid overload on Vpos supply in case of line transient (ex. ring trip detection).

The typical value is obtained for a sensing resistor equal to 110mΩ that will guarantee an average current consumption from Vpos < 700mA.

When in on-hook the self generated battery voltage is set to a predefined value.

This value can be adjusted via one external resistor (RF1) and it is typical -50V. When RING mode is selected this value is increased to -70V typ.

Once the line goes in off-hook condition, the DC/DC converter automatically adjust the generated battery voltage in order to feed the line with a fixed DC current (programmable via RLIM) optimising in this way the power dissipation.

OPERATING MODES

Power Down

DC CHARACTERISTIC & SUPERVISION

When this mode is selected the SLIC is switched off and the TIP and RING pins are in high impedance. Also the line detectors are disabled therefore the off-hook condition cannot be detected.

This mode can be selected in emergency condition when it is necessary to cut any current delivered to the line.

This mode is also forced by STLC3055 in case of thermal overload ($T_j > 140^{\circ}\text{C}$).

In this case the device goes back to the previous status as soon as the junction temperature decrease under the hysteresis threshold.

AC CHARACTERISTICS

The 2W port is set in high impedance, the TX output buffer is a low impedance output, no AC transmission is possible.

High Impedance Feeding (HI-Z)

DC CHARACTERISTIC & SUPERVISION

This operating mode is normally selected when the telephone is in on-hook in order to monitor the line status keeping the power consumption at the minimum.

The output voltage in on-hook condition is equal to the self generated battery voltage (-50V typ).

When off-hook occurs the $\overline{\text{DET}}$ becomes active (low logic level).

The off-hook threshold in HI-Z mode is the same value as programmed in ACTIVE mode.

The DC characteristic in HI-Z mode is just equal to the self generated battery with $2x(1500\Omega + R_p)$ in series (see fig.1), where R_p is the external protection resistance.

Figure 1. DC Characteristic in HI-Z Mode.

AC CHARACTERISTICS

The AC impedance shown at the 2W port (TIP/RING) is the same as the DC one. The TIP/RING AC impedance will be $2x(1500\Omega + R_p)$ or high impedance.

Active

DC CHARACTERISTICS & SUPERVISION

When this mode is selected the STLC3055 provides both DC feeding and AC transmission.

The STLC3055 feeds the line with a constant current fixed by RLIM (20mA to 40mA range). The on-hook voltage is typically 40V allowing on-hook transmission; the self generated Vbat is -50V typ.

If the loop resistance is very high and the line current cannot reach the programmed constant current feed value, the STLC3055 behaves like a 40V voltage source with a series impedance equal to the protection resistors $2xR_p$ (typ. $2x41\Omega$) plus the internal resistance. Fig. 2 shows the typical DC characteristic in ACTIVE mode.

Figure 2. DC characteristic in ACTIVE mode

The line status (on/off hook) is monitored by the SLIC's supervision circuit. The off-hook threshold can be programmed via the external resistor R_{TH} in the range from 5mA to 9mA.

Independently on the programmed constant current value, the TIP and RING buffers have a current source capability limited to 70mA typ.

Moreover the power available at Vbat is controlled by the DC/DC converter that limits the peak current drawn from the Vpos supply. The maximum allowed current peak is set by the R_{SENSE} resistor and it is typically 900mApk.

AC CHARACTERISTICS

The SLIC provides the standard SLIC transmission functions:

- **Input impedance synthesis:** can be real or complex and is set by a scaled (x50) external ZAC impedance.
- **Transmit and receive:** The AC signal present on the 2W port (TIP/RING) is transferred to the TX output with a -6dB gain and from the RX input to the 2W port with a 0dB gain.
- **2 to 4 wire conversion:** The balance impedance can be real or complex, the proper cancellation is obtained by means of two external impedance ZA and ZB.

Once in Active mode (D1=1) the SLIC can operate in different states setting properly D0 and D2 control bits (see also Table 2).

Table 2. SLIC states in ACTIVE mode

D0	D1	D2	Operating Mode
0	1	0	Active Normal Polarity
0	1	1	Active Reverse Polarity
1	1	0	Active TTX injection (N.P.)
1	1	1	Active TTX injection (R.P.)

POLARITY REVERSAL

The D2 bit controls the line polarity, the transition between the two polarities is performed in a "soft" way. This means that the TIP and RING wire exchange their polarities following a ramp transition (see fig.3). The transition time is controlled by an external capacitor CREV. This capacitor is also setting the shape of the ringing trapezoidal waveform.

When the control pins set battery reversal the line polarity is reversed with a proper transition time set via an external capacitor (CREV).

Figure 3. TIP/RING typical transition from Direct to Reverse Polarity

METERING PULSE INJECTION (TTX)

The metering pulses circuit consist of a burst shaping generator that gives a square wave shaped and a low pass filter to reduce the harmonic distortion of the output signal.

The metering pulse is obtained starting from two logic signals:

- CKTTX: is a square wave at the TTX frequency (12 or 16KHz) and should be permanently applied to the CKTTX pin or at least for all the duration of the TTX pulse (including rising and decay phases).
- D0: enable the TTX generation circuit and define the TTX pulse duration.

This two signals are then processed by a dedicated circuitry integrated on chip that generate the metering pulse as an amplitude modulated shaped squarewave (SQTTX) (see fig.4).

Both the amplitude and the envelope of the squarewave (SQTTX) can be programmed by means of external components. In particular the amplitude is set by the two resistors RLV and the

Figure 4. Metering pulse generation circuit.

shaping by the capacitor CS.

The waveform so generated is then filtered and injected on the line.

The low pass filter can be obtained using the integrated buffer OP1 connected between pin FTTX (OP1 non inverting input) and RTTX (OP1 output) (see fig.4) and implementing a "Sallen and Key" configuration.

Depending on the external components count it is possible to build an optimised application depending on the distortion level required. In particular harmonic distortion levels equal to 13%, 6% and 3% can be obtained respectively with first, second and third order filters (see fig.4).

The circuit showed in the "Application diagram" is related to the simple first order filter.

Once the shaped and filtered signal is obtained at RTTX buffer output it is injected on the TIP/RING pins with a +6dB gain.

It should be noted that this is the nominal condition obtained in presence of ideal TTX echo cancellation (obtained via proper setting of RTTX and CTTX). In addition the effective level obtained on the line will depend on the line impedance, the protection resistor value and the series switch (SW1 or SW2) on resistance.

In the typical application (TTX line impedance = 200Ω, RP = 41Ω, SW1,2 on resistance = 9Ω and ideal TTX echo cancellation) the metering pulse level on the line will be 1.33 times the level applied to the RTTX pin.

As already mentioned the metering pulse echo cancellation is obtained by means of two external components (RTTX and CTTX) that should match the line impedance at the TTX frequency. This simple network has a double effect:

- Synthesise a low output impedance at the TIP/RING pins at the TTX frequency.
- Cut the eventual TTX echo that will be transferred from the line to the TX output.

Ringging

When this mode is selected STLC3055 self generate an higher negative battery (-70V typ.) in order to allow a balanced ringing signal of typically 65Vpeak.

In this condition both the DC and AC feedback loop are disabled and the SLIC line drivers operate as voltage buffers.

The ring waveform is obtained toggling the D2 control bit at the desired ring frequency. This bit in fact controls the line polarity (0=direct; 1=reverse). As in the ACTIVE mode the line voltage transition is performed with a ramp transition, obtaining in this way a trapezoidal balanced ring waveform (see fig.5).

The shaping is defined by the CREV external capacitor.

Selecting the proper capacitor value it is possible to get different crest factor values.

The following table shows the crest factor values

Figure 5. TIP/RING typical ringing waveform

obtained with a 20Hz and 25Hz ring frequency and with 1REN. This value are valid either with European or USA specification:

CREV	CREST FACTOR @20Hz	CREST FACTOR @25Hz
22nF	1.2	1.26
27nF	1.25	1.32
33nF	1.33	Not significant (*)

(*) Distorsion already less than 10%.

The ring trip detection is performed sensing the variation of the AC line impedance from on hook (relatively high) to off-hook (low). This particular ring trip method allows to operate without DC offset superimposed on the ring signal and therefore obtaining the maximum possible ring level on the load starting from a given negative battery.

It should be noted that such a method is optimised for operation on short loop applications and may not operate properly in presence of long loop applications ($> 500\Omega$).

Once ring trip is detected, the $\overline{\text{DET}}$ output is activated (logic level low), at this point the card controller or a simple logic circuit should stop the D2 toggling in order to effectively disconnect the ring signal and then set the STLC3055 in the proper operating mode (normally ACTIVE).

RING LEVEL IN PRESENCE OF MORE TELEPHONE IN PARALLEL

As already mentioned above the maximum current that can be drawn from the Vpos supply is controlled and limited via the external RSENSE.

This will limit also the power available at the self generated negative battery.

If for any reason the ringer load will be too high the self generated battery will drop in order to keep the power consumption to the fixed limit and therefore also the ring voltage level will be reduced.

In the typical application with $R_{\text{SENSE}} = 110\text{m}\Omega$ the peak current from Vpos is limited to about 900mA, which correspond to an average current of 700mA max. In this condition the STLC3055 can drive up to 3REN with a ring frequency $f_r = 25\text{Hz}$ ($1\text{REN} = 1800\Omega + 1.0\mu\text{F}$, European standard).

In order to drive up to 5REN ($1\text{REN} = 6930\Omega + 8\mu\text{F}$, US standard) it is necessary to modify the external components as follows:

$\text{CREV} = 15\text{nF}$

$\text{RD} = 2.2\text{K}\Omega$

Power On Requirements

In order to avoid damage to the device when Vpos is first applied it is recommended to keep all the logic inputs to a low logic level (0V) until Vpos is $> 5.5\text{V}$.

In case this power up sequence cannot be guaranteed it's recommended to connect a shottky diode (BAT46 or equivalent) between VBAT and BGND see figure below.

Figure 6. Shottky diode connection

Layout Recommendation

A properly designed PCB layout is a basic issue to guarantee a correct behaviour and good noise performances.

Particular care must be taken on the ground connection and in this case the star configuration allows surely to avoid possible problems (see Application Diagram Fig. 7).

The ground of the power supply (VPOS) has to be connected to the center of the star, let's call this point PGND. This point should show a resistance as low as possible, that means it should be a ground plane.

Noise sources can be identified in not enough good grounds, not enough low impedance supplies and parasitic coupling between PCB tracks and high impedance pins of the device.

In particular to avoid noise problems the layout should prevent any coupling between the DC/DC converter components and analog pins that are referred to AGND (ex: RD, IREF, RTH, RLIM, VF). As a first recommendation the components CV, L, D1, CVPOS, RSENSE should be kept as close as possible to each other and isolated from the other components.

Additional improvements can be obtained:

- decoupling the center of the star from the analog ground of STLC3055 using small chokes.
- adding a capacitor in the range of 100nF between VPOS and AGND in order to filter the switch frequency on VPOS.

External Components List

In order to properly define the external components value the following system parameters have to be defined:

- The AC input impedance shown by the SLIC at the line terminals "Zs" to which the return loss measurement is referred. It can be real (typ. 600Ω) or complex.
- The AC balance impedance, it is the equivalent impedance of the line "Zl" used for evaluation of the trans-hybrid loss performances (2/4 wire conversion). It is usually a complex impedance.
- The value of the two protection resistors Rp in series with the line termination.
- The line impedance at the TTX frequency "Zltx".
- The metering pulse level amplitude measured at line termination "VLOTTX". In case of low order filtering, VLOTTX represents the amplitude (Vrms) of the fundamental frequency component. (typ 12 or 16KHz).
- Pulse metering envelope rise and decay time constant "τ".
- The slope of the ringing waveform " $\Delta V_{TR}/\Delta T$ ".
- The value of the constant current limit current "Ilim".
- The value of the off-hook current threshold "ITH".
- The value of the ring trip rectified average threshold current "IRTH".
- The value of the required self generated negative battery "VBATR" in ring mode (max value is 70V). This value can be obtained from the desired ring peak level + 5V.
- The value of the maximum current peak sunk from Vpos "IPK".

EXTERNAL COMPONENTS

Name	Function	Formula	Typ. Value
RREF	Bias setting current	$RREF = 1.3/I_{bias}$ $I_{bias} = 50\mu A$	26k Ω 1%

RSENSE	DC/DC converter peak current limiting	$RSENSE = 100mV/I_{PK}$	110m Ω @ $I_{PK} = 900mA$
L (8)	DC/DC converter inductor	DC Resistance $\leq 0.1\Omega$ (9)	L=125 μH RFP1304PV (Manuf.: All Inductive) or SUMIDA CDRH125 or equivalent
CF1	DC/DC converter feedback loop stability		220pF to 470pF (10)
RF1	Negative battery programming level	$250K\Omega < RF1 < 300K\Omega$ (7)	300kW 1% @ $V_{BATR} = -70V$
RF2	Negative battery programming level		9.1k Ω 1%

(1) In case $Z_s = Z_l$, Z_A and Z_B can be replaced by two resistors of same value: $R_A = R_B = |Z_s|$.

(2) In this case CTTX is just operating as a DC decoupling capacitor ($f_p = 100Hz$).

(3) Defining ZTTX as the impedance of RTTX in series with CTTX, RTTX and CTTX can also be calculated from the following formula:

$$Z_{TTX} = 50 * (Z_{ltx} + 2R_p + 18\Omega)$$

(4) CVpos should be defined depending on the power supply current capability and maximum allowable ripple.

(5) For low ripple application use 2x47 μF in parallel.

(6) Can be saved if proper PCB layout avoid noise coupling on RD pin (high impedance input).

(7) RF1 sets the self generated battery voltage in RING and ACTIVE($I_L=0$) mode as follows:

	267k Ω	280k Ω	294kW	300k Ω
$V_{BAT(ACTIVE)}$	-46V	-48V	-49V	-50V
$V_{BATR(RING)}$	-62V	-65V	-68V	-70V

V_{BATR} should be defined considering the ring peak level required ($V_{ringpeak} = V_{BATR} - 6V$ typ.).

The above relation is valid provided that the Vpos power supply current capability and the RSENSE programming allow to source all the current requested by the particular ringer load configuration.

(8) Core: MICROMETALS T50-26C IRON POWDER, AL-VALUE 61nH/N2

Current rating: 2A (50/60Hz)

Operating Temperature -25° to +60° Centigrades

Inductance: 14 μH +/-15% at 1KHz, 1mA

DC resistance of winding: MAX.100 mOhm

Code: RFY1303

Wire: UEW2, 0,60 mm

Turns: 50

Inductance ($f=1KHz$): >125 μH

(9) For high efficiency in HI-Z mode coil resistance @125kHz must be <3ohm

(10) Function of this capacitor is to introduce a zero at the resonance frequency for loop stability. In case some parasitic resistance are already present in the loop (Coil, CVBAT, PCB layout), the presence of this capacitor can degrade the device noise performances; in this case CF1 should be removed being the loop stability already guaranteed by the parasitic resistance.

ELECTRICAL CHARACTERISTICS

Test conditions: $V_{pos} = 6.0V$, AGND = BGND, Normal Polarity, $T_{amb} = 25^{\circ}C$.

External components as listed in the "Typical Values" column of EXTERNAL COMPONENTS Table.

Note: Testing of all parameter is performed at $25^{\circ}C$. Characterisation as well as design rules used allow correlation of tested performances at other temperatures. All parameters listed here are met in the operating range: -40 to $+85^{\circ}C$.

DC CHARACTERISTICS						
Symbol	Parameter	Test Condition	Min.	Typ.	Max.	Unit
V_{lohi}	Line voltage	II = 0, HI-Z (High impedance feeding) $T_{amb} = 0$ to $85^{\circ}C$	44	50		V
V_{lohi}	Line voltage	II = 0, HI-Z (High impedance feeding) $T_{amb} = -40$ to $85^{\circ}C$	42	48		V
V_{loa}	Line voltage	II = 0, ACTIVE $T_{amb} = 0$ to $85^{\circ}C$	33	40		V
V_{loa}	Line voltage	II = 0, ACTIVE $T_{amb} = -40$ to $85^{\circ}C$	31	37		V
Ilim	Lim. current programming range	ACTIVE mode	20		40	mA
Ilima	Lim. current accuracy	ACTIVE mode. Rel. to programmed value 20mA to 40mA	-10		10	mA
Rfeed HI	Feeding resistance	HI-Z (High Impedance feeding)	2.4		3.6	$k\Omega$
Zrx	RX port input impedance		280			$k\Omega$
AC CHARACTERISTICS						
L/T	Long. to transv. (see Appendix for test circuit)	$R_p = 41\Omega$, 1% tol., ACTIVE N. P., $R_L = 600\Omega$ (*) $f = 300$ to $3400Hz$	48	50		dB
T/L	Transv. to long. (see Appendix for test circuit)	$R_p = 41\Omega$, 1% tol., ACTIVE N. P., $R_L = 600\Omega$ (*) $f = 300$ to $3400Hz$	40	45		dB
T/L	Transv. to long. (see Appendix for test circuit)	$R_p = 41\Omega$, 1% tol., ACTIVE N. P., $R_L = 600\Omega$ (*) $f = 1kHz$	48	53		dB
2WRL	2W return loss	300 to 3400Hz, ACTIVE N. P., $R_L = 600\Omega$ (*)	22	26		dB
THL	Trans-hybrid loss	300 to 3400Hz, $20\log V_{RX}/V_{TX} $, ACTIVE N. P., $R_L = 600\Omega$ (*)	30			dB

Ipk	Peak current limiting accuracy	RING Off-Hook RSENSE = 110mΩ	-20%	950	+20%	mApk

APPENDIX A

STLC3055 Test Circuits

Referring to the application diagram shown in fig. 7 of the STLC3055 datasheet and using as external components the Typ. Values specified in the "External Components" Table (page 13) find below the proper configuration for each measurement.

All measurements requiring DC current termination should be performed using "Wandel & Goltermann DC Loop Holding Circuit GH-1" or equivalent.

Figure A1. 2W Return Loss

$$2WRL = 20\text{Log}(|Z_{ref} + Z_s|/|Z_{ref} - Z_s|) = 20\text{Log}(E/2V_s)$$

Figure A2. THL Trans Hybrid Loss

$$THL = 20\text{Log}|V_{rx}/V_{tx}|$$

Figure A3. G24 Transmit Gain
 $G_{24} = 20\text{Log}|2V_{tx}/E|$

Figure A4. G42 Receive Gain
 $G_{42} = 20\text{Log}|V_I/V_{rx}|$

Figure A5. PSRRC Power supply rejection Vpos to 2W port
 $PSSRC = 20\text{Log}|V_n/V_I|$

Figure A6. L/T Longitudinal to Transversal Conversion
 $L/T = 20\text{Log}|V_{cm}/V_I|$

Figure A7. T/L Transversal to Longitudinal Conversion
 $T/L = 20\text{Log}|V_{rx}/V_{cm}|$

Figure A8. VTTX Metering Pulse level on line

Figure A9. V2Wp and W4Wp: Idle channel psophometric noise at line and TX.
 $V2Wp = 20\text{Log}|V_I/0.774I|$; $V4Wp = 20\text{Log}|V_{tx}/0.774I|$
