

### Features

- Supports 133-MHz bus operations
- 256K × 36/512K × 18 common I/O
- 3.3V –5% and +10% core power supply (V<sub>DD</sub>)
- 2.5V or 3.3V I/O supply (V<sub>DDQ</sub>)
- Fast clock-to-output times
- 6.5 ns (133-MHz version)
- 7.5 ns (117-MHz version)
- 8.5 ns (100-MHz version)
- Provide high-performance 2-1-1-1 access rate
- User-selectable burst counter supporting Intel<sup>®</sup> Pentium<sup>®</sup> interleaved or linear burst sequences
- · Separate processor and controller address strobes
- Synchronous self-timed write
- · Asynchronous output enable
- Available in Lead-Free 100 TQFP,119 BGA and 165 fBGA packages Both 2 and 3 Chip Enable Options for TQFP
- IEEE 1149.1 compatible JTAG Boundary Scan for BGA and fBGA packages
- •"ZZ" Sleep Mode option

### **Functional Description**<sup>[1]</sup>

The CY7C1361C/CY7C1363C is a 3.3V, 256K x 36 and 512K x 18 Synchronous Flowthrough SRAMs, respectively designed to interface with high-speed microprocessors with minimum glue logic. Maximum access delay from clock rise is 6.5 ns (133-MHz version). A 2-bit on-chip counter captures the first address in a burst and increments the address automatically for the rest of the burst access. All synchronous inputs are gated by registers controlled by a positive-edge-triggered Clock Input (CLK). The synchronous inputs include all addresses, all data inputs, address-pipelining Chip Enable ( $\overline{CE}_1$ ), depth-expansion Chip Enables ( $CE_2$  and  $\overline{CE}_3$ <sup>[2]</sup>), Burst Control inputs (ADSC, ADSP, and ADV), Write Enables ( $\overline{BW}_x$ , and  $\overline{BWE}$ ), and Global Write ( $\overline{GW}$ ). Asynchronous inputs include the Output Enable ( $\overline{OE}$ ) and the ZZ pin.

The CY7C1361C/CY7C1363C allows either interleaved or linear burst sequences, selected by the MODE input pin. A HIGH selects an interleaved burst sequence, while a LOW selects a linear burst sequence. Burst accesses can be initiated with the Processor Address Strobe (ADSP) or the cache Controller Address Strobe (ADSC) inputs. Address advancement is controlled by the Address Advancement (ADV) input.

Addresses and chip enables are registered at rising edge of clock when either Address Strobe Processor ( $\overline{ADSP}$ ) or Address Strobe Controller ( $\overline{ADSC}$ ) are active. Subsequent burst addresses can be internally generated as controlled by the Advance pin ( $\overline{ADV}$ ).

The CY7C1361C/CY7C1363C operates from a +3.3V core power supply while all outputs may operate with either a +2.5 or +3.3V supply. All inputs and outputs are JEDEC-standard JESD8-5-compatible.

### **Selection Guide**

|                              | 133 MHz | 117 MHz | 100 MHz | Unit |
|------------------------------|---------|---------|---------|------|
| Maximum Access Time          | 6.5     | 7.5     | 8.5     | ns   |
| Maximum Operating Current    | 250     | 220     | 180     | mA   |
| Maximum CMOS Standby Current | 30      | 30      | 30      | mA   |

Notes:

1. For best-practices recommendations, please refer to the Cypress application note System Design Guidelines on www.cypress.com.

2.  $\overline{\text{CE}_3}$  is for A version of TQFP ( 3 Chip Enable Option) and 165 fBGA package only. 119 BGA is offered only in 2 Chip Enable.

## **Pin Definitions**

| Name   | I/O                    | Description   |
|--|------------------------|---|
| A <sub>0</sub> , A <sub>1</sub> , A                                  | Input-<br>Synchronous  | <b>Address Inputs used to select one of the address</b> <u>locations</u> . Sampled at the rising edge of the CLK if ADSP or ADSC is active LOW, and $CE_1$ , $CE_2$ , and $CE_3^{[2]}$ are sampled active. $A_{[1:0]}$ feed the 2-bit counter.  |
| BW <sub>A</sub> ,BW <sub>B</sub><br>BW <sub>C</sub> ,BW <sub>D</sub> | Input-<br>Synchronous  | Byte Write Select Inputs, active LOW. Qualified with BWE to conduct byte writes to the SRAM. Sampled on the rising edge of CLK.   |
| GW   | Input-<br>Synchronous  | <b>Global Write Enable Input, active LOW</b> . When asserted LOW on the rising edge of CLK, a global write is conducted (ALL bytes are written, regardless of the values on $BW_X$ and $BWE$ ).   |
| CLK  | Input-<br>Clock        | <b>Clock Input</b> . Used to capture all synchronous inputs to the device. Also used to increment the burst counter when ADV is asserted LOW, during a burst operation.   |
| CE <sub>1</sub>  | Input-<br>Synchronous  | <b>Chip Enable 1 Input, active LOW</b> . Sampled on the rising edge of <u>C</u> LK. Used in conjunction with $CE_2$ and $CE_3^{[2]}$ to select/deselect the device. ADSP is ignored if $\overline{CE}_1$ is HIGH. $\overline{CE}_1$ is sampled only when a new external address is loaded.  |
| CE <sub>2</sub>  | Input-<br>Synchronous  | <b>Chip Enable 2 Input, active HIGH</b> . Sampled on the rising edge of CLK. Used in conjunction with $CE_1$ and $CE_3^{[2]}$ to select/deselect the device. $CE_2$ is sampled only when a new external address is loaded.  |
| CE <sub>3</sub> <sup>[2]</sup>                                       | Input-<br>Synchronous  | <b>Chip Enable 3 Input, active LOW</b> . Sampled on the rising edge of CLK. Used in conjunction with $CE_1$ and $CE_2$ to select/ deselect the device. $CE_3$ is sampled only when a new external address is loaded.  |
| ŌĒ   | Input-<br>Asynchronous | <b>Output Enable, asynchronous input, active LOW</b> . Controls the direction of the I/O pins. When LOW, the I/O pins behave as out <u>puts</u> . When deasserted HIGH, I/O pins are three-stated, and act as input data pins. OE is masked during the first clock of a read cycle when emerging from a deselected state.   |
| ADV  | Input-<br>Synchronous  | Advance Input signal, sampled on the rising edge of CLK. When asserted, it automat-<br>ically increments the address in a burst cycle.  |
| ADSP   | Input-<br>Synchronous  | Address Strobe from Processor, sampled on the rising edge of CLK, active LOW. When asserted LOW, addresses presented to the device are <u>captured</u> in the <u>a</u> ddress registers. $A_{[1:0]}$ are also loaded into the <u>burst</u> counter. When ADSP and ADSC are both asserted, only ADSP is recognized. ASDP is ignored when $\overline{CE}_1$ is deasserted HIGH.   |
| ADSC   | Input-<br>Synchronous  | Address Strobe from Controller, sampled on the rising edge of CLK, active LOW.<br>When asserted LOW, addresses presented to the device are <u>captured</u> in the address<br>registers. $A_{[1:0]}$ are also loaded into the burst counter. When ADSP and ADSC are both<br>asserted, only ADSP is recognized.   |
| BWE  | Input-<br>Synchronous  | Byte Write Enable Input, active LOW. Sampled on the rising edge of CLK. This signal must be asserted LOW to conduct a byte write.   |
| ZZ   | Input-<br>Asynchronous | <b>ZZ</b> "sleep" Input, active HIGH. When asserted HIGH places the device in a non-time-critical "sleep" condition with data integrity preserved. For normal operation, this pin has to be LOW or left floating. ZZ pin has an internal pull-down.   |
| DQ <sub>s</sub>  | I/O-<br>Synchronous    | <b>Bidirectional Data I/O lines</b> . As inputs, they feed into an on-chip data register that is triggered by the rising edge of CLK. As outputs, they deliver the data contained in the memory location specified by the addresses presented during the previous clock rise of the read cycle. The direction of the pins is controlled by $\overline{OE}$ . When $\overline{OE}$ is asserted LOW, the pins behave as outputs. When HIGH, $DQ_s$ and $DQP_X$ are placed in a three-state condition. The outputs are automatically three-stated during the data portion of a write sequence, during the first clock when emerging from a deselected state, and when the device is deselected, regardless of the state of $\overline{OE}$ . |
| DQP <sub>X</sub>   | I/O-<br>Synchronous    | <b>Bidirectional Data Parity I/O Lines</b> . Functionally, these signals are identical to $DQ_s$ .<br>During write sequences, $DQP_X$ is controlled by $BW_X$ correspondingly.  |
| MODE   | Input-<br>Static       | <b>Selects Burst Order</b> . When tied to GND selects linear burst sequence. When tied to $V_{DD}$ or left floating selects interleaved burst sequence. This is a strap pin and should remain static during device operation. Mode Pin has an internal pull-up.   |
| V <sub>DD</sub>  | Power Supply           | Power supply inputs to the core of the device.  |
| V <sub>DDQ</sub>   | I/O Power Supply       | Power supply for the I/O circuitry.   |
| V <sub>SS</sub>  | Ground                 | Ground for the core of the device.  |

## Pin Definitions (continued)

| Name                 | I/O                               | Description  |
|----------------------|-----------------------------------|--|
| V <sub>SSQ</sub>     | I/O Ground                        | Ground for the I/O circuitry.  |
| TDO                  | JTAG serial output<br>Synchronous | Serial data-out to the JTAG circuit. Delivers data on the negative edge of TCK. If the JTAG feature is not being utilized, this pin should be left unconnected. This pin is not available on TQFP packages.  |
| TDI                  |                                   | <b>Serial data-In to the JTAG circuit</b> . Sampled on the rising edge of TCK. If the JTAG feature is not being utilized, this pin can be left floating or connected to $V_{DD}$ through a pull up resistor. This pin is not available on TQFP packages. |
| TMS                  |                                   | Serial data-In to the JTAG circuit. Sampled on the rising edge of TCK. If the JTAG feature is not being utilized, this pin can be disconnected or connected to $V_{DD}$ . This pin is not available on TQFP packages.                                    |
| ТСК                  | JTAG-<br>Clock                    | <b>Clock input to the JTAG circuitry</b> . If the JTAG feature is not being utilized, this pin must be connected to $V_{SS}$ . This pin is not available on TQFP packages.   |
| NC                   | -                                 | <b>No Connects</b> . Not internally connected to the die. 18M, 36M, 72M, 144M and 288M are address expansion pins are not internally connected to the die.   |
| V <sub>SS</sub> /DNU | Ground/DNU                        | This pin can be connected to Ground or should be left floating.  |

## Functional Overview

All synchronous inputs pass through input registers controlled by the rising edge of the clock. Maximum access delay from the clock rise ( $t_{CDV}$ ) is 6.5 ns (133-MHz device).

The CY7C1361C/CY7C1363C supports secondary cache in systems utilizing either a linear or interleaved burst sequence. The interleaved burst order supports Pentium<sup>®</sup> and i486 processors. The linear burst sequence is suited for processors that utilize a linear burst sequence. The burst order is user-selectable, and is determined by sampling the MODE input. Accesses can be initiated with either the Processor Address Strobe (ADSP) or the Controller Address Strobe (ADSC). Address advancement through the burst sequence is controlled by the ADV input. A two-bit on-chip wraparound burst counter captures the first address in a burst sequence and automatically increments the address for the rest of the burst access.

Byte write operations are qualified with the Byte Write Enable  $(\overline{BWE})$  and Byte Write Select  $(\overline{BWX})$  inputs. A Global Write Enable  $(\overline{GW})$  overrides all byte write inputs and writes data to all four bytes. All writes are simplified with on-chip synchronous self-timed write circuitry.

Three synchronous Chip Selects  $(\overline{CE}_1, CE_2, \overline{CE}_3^{[2]})$  and an asynchronous Output Enable ( $\overline{OE}$ ) provide for easy bank selection and output three-state control. ADSP is ignored if  $\overline{CE}_1$  is HIGH.

#### Single Read Accesses

A single read access is initiated when the following conditions are satisfied at clock rise: (1)  $\overline{CE}_{1.}$   $\underline{CE}_{2}$ , and  $\overline{CE}_{3}^{[2]}$  are all asserted active, and (2) ADSP or ADSC is asserted LOW (if the access is initiated by ADSC, the write inputs must be deasserted during this first cycle). The address presented to the address inputs is latched into the address register and the burst counter/control logic and presented to the memory core. If the OE input is asserted LOW, the requested data will be available at the data outputs a maximum to  $t_{CDV}$  after clock rise. ADSP is ignored if CE<sub>1</sub> is HIGH.

#### Single Write Accesses Initiated by ADSP

This access is initiated when the following conditions are satisfied at clock rise: (1)  $CE_1$ ,  $CE_2$ ,  $CE_3$ <sup>[2]</sup> are all asserted active, and (2) ADSP is asserted LOW. The addresses presented are loaded into the address register and the burst inputs (GW, BWE, and BW<sub>X</sub>) are ignored during this first clock cycle. If the write inputs are asserted active (see Write Cycle Descriptions table for appropriate states that indicate a write) on the next clock rise, the appropriate data will be latched and written into the device. Byte writes are allowed. All I/Os are three-stated during a byte write. Since this is a common I/O device, the asynchronous OE input signal must be deasserted and the I/Os must be three-stated prior to the presentation of data to DQs. As a safety precaution, the data lines are three-stated once a write cycle is detected, regardless of the state of OE.

#### Single Write Accesses Initiated by ADSC

This write access is initiated when the following conditions are satisfied at clock rise: (1)  $\overline{CE}_1$ ,  $\overline{CE}_2$ , and  $\overline{CE}_3^{[2]}$  are all asserted

active, (2)  $\overline{\text{ADSC}}$  is asserted LOW, (3)  $\overline{\text{ADSP}}$  is deasserted HIGH, and (4) the write input signals ( $\overline{\text{GW}}$ ,  $\overline{\text{BWE}}$ , and  $\overline{\text{BW}}_X$ ) indicate a write access. ADSC is ignored if ADSP is active LOW. The addresses presented are loaded into the address register and the burst counter/control logic and delivered to the memory core. The information presented to  $DQ_{[A:D]}$  will be written into the specified address location. Byte writes are allowed. All I/Os are three-stated when a write is detected, even a byte write. Since this is a common I/O device, the asynchronous  $\overline{OE}$  input signal must be deasserted and the I/Os must be three-stated prior to the presentation of data to DQs. As a safety precaution, the data lines are three-stated once a write cycle is detected, regardless of the state of  $\overline{OE}$ .

#### **Burst Sequences**

The CY7C1361C/CY7C1363C provides an on-chip two-bit wraparound burst counter inside the SRAM. The burst counter is fed by  $A_{[1:0]}$ , and can follow either a linear or interleaved burst order. The burst order is determined by the state of the MODE input. A LOW on MODE will select a linear burst sequence. A HIGH on MODE will select an interleaved burst order. Leaving MODE unconnected will cause the device to default to a interleaved burst sequence.

### Interleaved Burst Address Table (MODE = Floating or VDD)

| First<br>Address<br>A1: A0 | Second<br>Address<br>A1: A0 | Third<br>Address<br>A1: A0 | Fourth<br>Address<br>A1: A0 |
|----------------------------|-----------------------------|----------------------------|-----------------------------|
| 00                         | 01                          | 10                         | 11                          |
| 01                         | 00                          | 11                         | 10                          |
| 10                         | 11                          | 00                         | 01                          |
| 11                         | 10                          | 01                         | 00                          |

### Linear Burst Address Table (MODE = GND)

|                            |                             | •                          | ,                           |
|----------------------------|-----------------------------|----------------------------|-----------------------------|
| First<br>Address<br>A1: A0 | Second<br>Address<br>A1: A0 | Third<br>Address<br>A1: A0 | Fourth<br>Address<br>A1: A0 |
| 00                         | 01                          | 10                         | 11                          |
| 01                         | 10                          | 11                         | 00                          |
| 10                         | 11                          | 00                         | 01                          |
| 11                         | 00                          | 01                         | 10                          |

#### Sleep Mode

The ZZ input pin is an asynchronous input. Asserting ZZ places the SRAM in a power conservation "sleep" mode. Two clock cycles are required to enter into or exit from this "sleep" mode. While in this mode, data integrity is guaranteed. Accesses pending when entering the "sleep" mode are not considered valid nor is the completion of the operation guaranteed. The device must be deselected prior to entering the "sleep" mode.  $\overline{CE}_1$ ,  $\overline{CE}_2$ ,  $\overline{CE}_3^{[2]}$ ,  $\overline{ADSP}$ , and  $\overline{ADSC}$  must remain inactive for the duration of  $t_{ZZREC}$  after the ZZ input returns LOW.

### **ZZ Mode Electrical Characteristics**

| Parameter          | Description                       | Test Conditions           | Min.              | Max.              | Unit |
|--------------------|-----------------------------------|---------------------------|-------------------|-------------------|------|
| I <sub>DDZZ</sub>  | Sleep mode standby current        | $ZZ \ge V_{DD} - 0.2V$    |                   | 35                | mA   |
| t <sub>ZZS</sub>   | Device operation to ZZ            | $ZZ \ge V_{DD} - 0.2V$    |                   | 2t <sub>CYC</sub> | ns   |
| t <sub>ZZREC</sub> | ZZ recovery time                  | ZZ <u>&lt;</u> 0.2V       | 2t <sub>CYC</sub> |                   | ns   |
| t <sub>ZZI</sub>   | ZZ active to sleep current        | This parameter is sampled |                   | 2t <sub>CYC</sub> | ns   |
| t <sub>RZZI</sub>  | ZZ Inactive to exit sleep current | This parameter is sampled | 0                 |                   | ns   |

#### Truth Table [3, 4, 5, 6, 7]

| Cycle Description            | Address<br>Used | CE <sub>1</sub> | CE <sub>2</sub> | CE <sub>3</sub> | zz | ADSP | ADSC | ADV | WRITE | OE | CLK | DQ          |

Notes:

Notes:
3. <u>X="Don</u>'t Care." H = Logic HIGH, L = Logic LOW.
4. WRITE = L when any one or more Byte Write enable signals and <u>BWE</u> = L or <u>GW</u>= L. WRITE = H when all Byte write enable signals , <u>BWE</u>, <u>GW</u> = H..
5. The DQ pins are controlled by the current cycle and the <u>OE</u> signal. <u>OE</u> is asynchronous and is <u>not</u> sampled with the clock.
6. The <u>SRAM</u> always initiates a read <u>cycle</u> when ADSP is <u>asserted</u>, regardless of the state of <u>GW</u>, <u>BWE</u>, or <u>BW<sub>x</sub></u>. Writes may occur only on subsequent clocks after the <u>ADSP</u> or with the assertion of <u>ADSC</u>. As a result, <u>OE</u> must be driven HIGH prior to the start of the write cycle to allow the outputs to three-state. <u>OE</u> is a don't care for the remainder of the write cycle.

7. OE is asynchronous and is not sampled with the clock rise. It is masked internally during write cycles. During a read cycle all data bits are three-state when OE is inactive or when the device is deselected, and all data bits behave as output when OE is active (LOW).

Note:

8. Table only lists a partial listing of the byte write combinations. Any Combination of  $\overline{BW}_{\chi}$  is valid Appropriate write will be done based on which byte write is active.

## IEEE 1149.1 Serial Boundary Scan (JTAG)

The CY7C1361C/CY7C1363C incorporates a serial boundary scan test access port (TAP) in the BGA package only. The TQFP package does not offer this functionality. This part operates in accordance with IEEE Standard 1149.1-1900, but doesn't have the set of functions required for full 1149.1 compliance. These functions from the IEEE specification are excluded because their inclusion places an added delay in the critical speed path of the SRAM. Note the TAP controller functions in a manner that does not conflict with the operation of other devices using 1149.1 fully compliant TAPs. The TAP operates using JEDEC-standard 3.3V or 2.5V I/O logic levels.

The CY7C1361C/CY7C1363C contains a TAP controller, instruction register, boundary scan register, bypass register, and ID register.

#### Disabling the JTAG Feature

It is possible to operate the SRAM without using the JTAG feature. To disable the TAP controller, TCK must be tied LOW (V<sub>SS</sub>) to prevent clocking of the device. TDI and TMS are internally pulled up and may be unconnected. They may alternately be connected to V<sub>DD</sub> through a pull-up resistor. TDO should be left unconnected. Upon power-up, the device will come up in a reset state which will not interfere with the operation of the device.

### TAP Controller State Diagram

The 0/1 next to each state represents the value of TMS at the rising edge of TCK.

### Test Access Port (TAP)

#### Test Clock (TCK)

The test clock is used only with the TAP controller. All inputs are captured on the rising edge of TCK. All outputs are driven from the falling edge of TCK.

### Test MODE SELECT (TMS)

The TMS input is used to give commands to the TAP controller and is sampled on the rising edge of TCK. It is allowable to leave this ball unconnected if the TAP is not used. The ball is pulled up internally, resulting in a logic HIGH level.

#### Test Data-In (TDI)

The TDI ball is used to serially input information into the registers and can be connected to the input of any of the registers. The register between TDI and TDO is chosen by the instruction that is loaded into the TAP instruction register. For information on loading the instruction register, see **Figure**. TDI is internally pulled up and can be unconnected if the TAP is unused in an application. TDI is connected to the most significant bit (MSB) of any register. (See Tap Controller Block Diagram.)

#### Test Data-Out (TDO)

The TDO output ball is used to serially clock data-out from the registers. The output is active depending upon the current state of the TAP state machine. The output changes on the falling edge of TCK. TDO is connected to the least significant bit (LSB) of any register. (See Tap Controller State Diagram.)

### **TAP Controller Block Diagram**

### Performing a TAP Reset

A RESET is performed by forcing TMS HIGH ( $V_{DD}$ ) for five rising edges of TCK. This RESET does not affect the operation of the SRAM and may be performed while the SRAM is operating.

At power-up, the TAP is reset internally to ensure that TDO comes up in a High-Z state.

#### **TAP Registers**

Registers are connected between the TDI and TDO balls and allow data to be scanned into and out of the SRAM test circuitry. Only one register can be selected at a time through the instruction register. Data is serially loaded into the TDI ball on the rising edge of TCK. Data is output on the TDO ball on the falling edge of TCK.

#### Instruction Register

Three-bit instructions can be serially loaded into the instruction register. This register is loaded when it is placed between the TDI and TDO balls as shown in the Tap Controller Block Diagram. Upon power-up, the instruction register is loaded with the IDCODE instruction. It is also loaded with the IDCODE instruction if the controller is placed in a reset state as described in the previous section.

When the TAP controller is in the Capture-IR state, the two least significant bits are loaded with a binary "01" pattern to allow for fault isolation of the board-level serial test data path.

#### **Bypass Register**

To save time when serially shifting data through registers, it is sometimes advantageous to skip certain chips. The bypass register is a single-bit register that can be placed between the TDI and TDO balls. This allows data to be shifted through the SRAM with minimal delay. The bypass register is set LOW  $(V_{SS})$  when the BYPASS instruction is executed.

#### Boundary Scan Register

The boundary scan register is connected to all the input and bidirectional balls on the SRAM.

The boundary scan register is loaded with the contents of the RAM I/O ring when the TAP controller is in the Capture-DR state and is then placed between the TDI and TDO balls when the controller is moved to the Shift-DR state. The EXTEST, SAMPLE/PRELOAD and SAMPLE Z instructions can be used to capture the contents of the I/O ring.

The Boundary Scan Order tables show the order in which the bits are connected. Each bit corresponds to one of the bumps on the SRAM package. The MSB of the register is connected to TDI and the LSB is connected to TDO.

#### Identification (ID) Register

The ID register is loaded with a vendor-specific, 32-bit code during the Capture-DR state when the IDCODE command is loaded in the instruction register. The IDCODE is hardwired into the SRAM and can be shifted out when the TAP controller is in the Shift-DR state. The ID register has a vendor code and other information described in the Identification Register Definitions table.

#### **TAP Instruction Set**

#### Overview

Eight different instructions are possible with the three-bit instruction register. All combinations are listed in the Instruction Codes table. Three of these instructions are listed as RESERVED and should not be used. The other five instructions are described in detail below.

The TAP controller used in this SRAM is not fully compliant to the 1149.1 convention because some of the mandatory 1149.1 instructions are not fully implemented.

The TAP controller cannot be used to load address data or control signals into the SRAM and cannot preload the I/O buffers. The SRAM does not implement the 1149.1 commands EXTEST or INTEST or the PRELOAD portion of SAMPLE/PRELOAD; rather, it performs a capture of the I/O ring when these instructions are executed. Instructions are loaded into the TAP controller during the Shift-IR state when the instruction register is placed between TDI and TDO. During this state, instructions are shifted through the instruction register through the TDI and TDO balls. To execute the instruction once it is shifted in, the TAP controller needs to be moved into the Update-IR state.

#### EXTEST

EXTEST is a mandatory 1149.1 instruction which is to be executed whenever the instruction register is loaded with all 0s. EXTEST is not implemented in this SRAM TAP controller, and therefore this device is not compliant to 1149.1. The TAP controller does recognize an all-0 instruction.

When an EXTEST instruction is loaded into the instruction register, the SRAM responds as if a SAMPLE/PRELOAD instruction has been loaded. There is one difference between the two instructions. Unlike the SAMPLE/PRELOAD instruction, EXTEST places the SRAM outputs in a High-Z state.

#### IDCODE

The IDCODE instruction causes a vendor-specific, 32-bit code to be loaded into the instruction register. It also places the instruction register between the TDI and TDO balls and allows the IDCODE to be shifted out of the device when the TAP controller enters the Shift-DR state.

The IDCODE instruction is loaded into the instruction register upon power-up or whenever the TAP controller is given a test logic reset state.

#### SAMPLE Z

The SAMPLE Z instruction causes the boundary scan register to be connected between the TDI and TDO balls when the TAP controller is in a Shift-DR state. It also places all SRAM outputs into a High-Z state.

#### SAMPLE/PRELOAD

SAMPLE/PRELOAD is a 1149.1-mandatory instruction. When the SAMPLE/PRELOAD instructions are loaded into the instruction register and the TAP controller is in the Capture-DR state, a snapshot of data on the inputs and output pins is captured in the boundary scan register.

The user must be aware that the TAP controller clock can only operate at a frequency up to 20 MHz, while the SRAM clock operates more than an order of magnitude faster. Because there is a large difference in the clock frequencies, it is possible that during the Capture-DR state, an input or output will undergo a transition. The TAP may then try to capture a signal while in transition (metastable state). This will not harm the device, but there is no guarantee as to the value that will be captured. Repeatable results may not be possible.

To guarantee that the boundary scan register will capture the correct value of a signal, the SRAM signal must be stabilized long enough to meet the TAP controller's capture set-up plus hold times ( $t_{CS}$  and  $t_{CH}$ ). The SRAM clock input might not be captured correctly if there is no way in a design to stop (or slow) the clock during a SAMPLE / PRELOAD instruction. If this is an issue, it is still possible to capture all other signals and simply ignore the value of the CK and CK# captured in the boundary scan register.

Once the data is captured, it is possible to shift out the data by putting the TAP into the Shift-DR state. This places the boundary scan register between the TDI and TDO pins.

PRELOAD allows an initial data pattern to be placed at the latched parallel outputs of the boundary scan register cells prior to the selection of another boundary scan test operation.

The shifting of data for the SAMPLE and PRELOAD phases can occur concurrently when required-that is, while data captured is shifted out, the preloaded data can be shifted in.

# **BYPASS**

When the BYPASS instruction is loaded in the instruction register and the TAP is placed in a Shift-DR state, the bypass register is placed between the TDI and TDO balls. The advantage of the BYPASS instruction is that it shortens the boundary scan path when multiple devices are connected together on a board.

#### Reserved

These instructions are not implemented but are reserved for future use. Do not use these instructions.

### **Identification Register Definitions**

| Instruction Field                    | CY7C1361C<br>(256K x36) | CY7C1363C<br>(512K x18) | Description                                  |
|--------------------------------------|-------------------------|-------------------------|--|
| Revision Number (31:29)              | 000                     | 000                     | Describes the version number.                |
| Device Depth (28:24) <sup>[12]</sup> | 01011                   | 01011                   | Reserved for Internal Use                    |
| Device Width (23:18)                 | 000001                  | 000001                  | Defines memory type and architecture         |
| Cypress Device ID (17:12)            | 100110                  | 010110                  | Defines width and density                    |
| Cypress JEDEC ID Code (11:1)         | 00000110100             | 00000110100             | Allows unique identification of SRAM vendor. |
| ID Register Presence Indicator (0)   | 1                       | 1                       | Indicates the presence of an ID register.    |

Note:

All voltages referenced to Vss (GND).
 Bit #24 is "1" in the Register Definitions for both 2.5v and 3.3v versions of this device.

## Scan Register Sizes

| Register Name                                  | Bit Size (×36) | Bit Size (×18) |
|--|----------------|----------------|
| Instruction                                    | 3              | 3              |
| Bypass   | 1              | 1              |
| ID   | 32             | 32             |
| Boundary Scan Order<br>(119-ball BGA package)  | 71             | 71             |
| Boundary Scan Order<br>(165-ball fBGA package) | 71             | 71             |

## **Identification Codes**

| Instruction    | Code | Description  |
|----------------|------|--|
| EXTEST         | 000  | Captures I/O ring contents. Places the boundary scan register between TDI and TDO. Forces all SRAM outputs to High-Z state.                |
| IDCODE         | 001  | Loads the ID register with the vendor ID code and places the register between TDI and TDO. This operation does not affect SRAM operations. |
| SAMPLE Z       | 010  | Captures I/O ring contents. Places the boundary scan register between TDI and TDO.<br>Forces all SRAM output drivers to a High-Z state.    |
| RESERVED       | 011  | Do Not Use: This instruction is reserved for future use.   |
| SAMPLE/PRELOAD | 100  | Captures I/O ring contents. Places the boundary scan register between TDI and TDO. Does not affect SRAM operation.                         |
| RESERVED       | 101  | Do Not Use: This instruction is reserved for future use.   |
| RESERVED       | 110  | Do Not Use: This instruction is reserved for future use.   |
| BYPASS         | 111  | Places the bypass register between TDI and TDO. This operation does not affect SRAM operations.  |

| Notes:  |  | •                |      |         |      | •       |      |      |

Notes:

16. This part has a voltage regulator internally; t<sub>POWER</sub> is the time that the power needs to be supplied above V<sub>DD</sub>(minimum) initially, before a read or write operation can be initiated.

17. t<sub>CHZ</sub>, t<sub>CLZ</sub>, t<sub>OELZ</sub>, and t<sub>OEHZ</sub> are specified with AC test conditions shown in part (b) of AC Test Loads. Transition is measured ± 200 mV from steady-state voltage.
18. At any given voltage and temperature, t<sub>OEHZ</sub> is less than t<sub>OELZ</sub> and t<sub>CHZ</sub> is less than t<sub>CLZ</sub> to eliminate bus contention between SRAMs when sharing the same data bus. These specifications do not imply a bus contention condition, but reflect parameters guaranteed over worst case user conditions. Device is designed to achieve High-Z prior to Low-Z under the same system conditions
19. This parameter is sampled and not 100% tested.
20. Timite afformation surpliced to the same system conditions.

20. Timing reference level is 1.5V when V<sub>DDQ</sub> = 3.3V and is 1.25V when V<sub>DDQ</sub> = 2.5V. 21. Test conditions shown in (a) of AC Test Loads unless otherwise noted.

Timing Diagrams

#### Note:

22. On this diagram, when  $\overline{CE}$  is LOW:  $\overline{CE}_1$  is LOW,  $CE_2$  is HIGH and  $\overline{CE}_3$  is LOW. When  $\overline{CE}$  is HIGH:  $\overline{CE}_1$  is HIGH or  $CE_2$  is LOW or  $\overline{CE}_3$  is HIGH.

Timing Diagrams (continued) Write Cycle Timing<sup>[22, 23]</sup>

#### Notes:

23. Full width write can be initiated by either  $\overline{\text{GW}}$  LOW; or by  $\overline{\text{GW}}$  HIGH,  $\overline{\text{BWE}}$  LOW and  $\overline{\text{BW}}_{X}$  LOW.

### Timing Diagrams (continued) Read/Write Cycle Timing<sup>[22, 24, 25]</sup>

#### Notes:

24. The data bus (Q) remains in high-Z following a WRITE cycle, unless a new read access is initiated by ADSP or ADSC.

25. GW is HIGH.

26. Device must be deselected when entering ZZ mode. See Cycle Descriptions table for all possible signal conditions to deselect the device.

27. DQs are in high-Z when exiting ZZ sleep mode.

Timing Diagrams (continued) ZZ Mode Timing<sup>[26, 27]</sup>
