Remote Controller MCU
SST65P542R

FEATURES:

- **8-bit MCU Core**
  - Enhanced 6502 Microprocessor Megacell emulating the reduced 6805 instruction set
- **4 MHz Typical Oscillator Clock Frequency**
- **8 MHz Maximum Oscillator Clock Frequency**
- **Low Voltage Operation: 2.2-3.2V**
- **20 Re-configurable General Purpose I/O pins**
- **SuperFlash Memory**
  - 16 KByte of Flash Memory
  - 128 Byte sectors for SoftPartition
  - 100,000 endurance cycles (typical)
  - 100 years data retention
  - Fast Write:
    - Chip-Erase: 70 ms (typical)
    - Sector-Erase: 18 ms (typical)
    - Byte-Program: 60 µs (typical)
  - In-Application Programming (IAP)
- **External Host Programming Mode for Programmer Support**
  - JEDEC Standard Command Sets

- **352 Byte On-Chip SRAM**
- **In-System Programming (ISP) Support through Firmware**
- **IR Input Pin for Learning Mode**
- **Carrier Modulator Transmitter**
  - Supports Baseband, Pulse Length Modulator (PLM), and Frequency Shift Keying (FSK)
- **Core Timer / Counter**
  - 14-stage multifunctional ripple counter
  - Includes timer overflow, POR, RTI, and CWT
- **External Reset and Low Power Reset Pins**
  - One of these pins should be used to connect the external Power-on/Brown-out reset circuitry
- **Power Management**
  - Hardware enable bits programmable by software for entering STOP and IDLE modes
- **Package Available**
  - 28-lead SOIC
- **All non-Pb (lead-free) devices are RoHS compliant**

PRODUCT DESCRIPTION

The SST65P542R is a member of SST's 8-bit application-specific microcontroller family targeted for infrared remote controller applications.

The SST65P542R microcontroller provides high functionality to infrared remote controller products. The device offers flexibility to store different remote control configurations for controlling multiple appliances. The configurations are either programmed at the factory during the manufacturing process or downloaded through firmware.

Using SST's SuperFlash nonvolatile memory technology, the SST65P542R enhances the functionality and reduces the cost of conventional universal remote controller devices by integrating the multiple functions of a remote controller system in a single chip solution. The built-in LED I/O ports can directly drive LED indicators. The IR transmitter port drives signals to the infrared transmitter, which, in turn, remotely controls the appliances.

The SoftPartition architecture allows seamless flash memory partitioning of the program code, protocol tables, and user data in the small granularity of 128 Byte sectors. The small sector size and fast Write capability of the device greatly decreases the time and power when altering the contents of the flash memory.

The highly reliable, patented SuperFlash technology provides significant advantages over conventional flash memory technology. These advantages translate into significant cost savings and reliability benefits for customers.

2.1 Pin Descriptions

TABLE   2-1: PIN DESCRIPTIONS

Symbol	Type	Name and Functions
PA[7:0]	I/O[1]	**Port A:** The state of any pin in Port A is software programmable and every line is configured as an input during any reset.
PB[7:0]	I/O	**Port B:** The state of any pin in Port B is software programmable and every line is configured as an input during any reset. Each I/O line contains a programmable interrupt/pull-up for keyscan.
PC[3:0]	I/O	**Port C:** Every pin in Port C is a high-current pin and its state is software programmable. All lines are configured as inputs during any reset.
IRO	O	**IRO:** Suitable for driving IR LED biasing logic, the IRO pin is the high-current source and sink output of the carrier modulator transmitter subsystem. Default state is low after any reset.
LPRST#	I	**Low-Power Reset:** An active-low pin, LPRST# function sets MCU to low-power reset mode. Once the device is in low-power reset mode, it is held in reset with all processor clocks and crystal oscillator halted. An internal Schmitt trigger is included in the LPRST# pin to improve noise immunity.
RST#	I	**Reset:** By setting the RST# pin low, the device is reset to a default state. An internal Schmitt trigger is included in the RST# pin to improve noise immunity.
OSC1	I	**Oscillator 1,2:** These 2 pins interface with external oscillator circuits. A crystal
OSC2	O	resonator, a ceramic resonator, or an external clock signal can be used.
IRQ#	I	**Interrupt Request:** The IRQ# is negative edge-sensitive triggered. An internal Schmitt trigger is included in the IRQ# pin to improve noise immunity.
V_{DD}	PWR	**Power Supply:** Supply Voltage (2.2-3.2V)
V_{SS}	PWR	**Ground:** Circuit ground. (0V reference)

3.0 I/O REGISTERS AND MEMORY ORGANIZATION

The SST65P542R has a total of 64 KByte of addressable memory space. A memory map is located in Figure 3-1. The on-chip memory consists of 32 Bytes of I/O registers, 352 Bytes of SRAM, 16 KByte of user flash memory and 128 Bytes of user vectors.

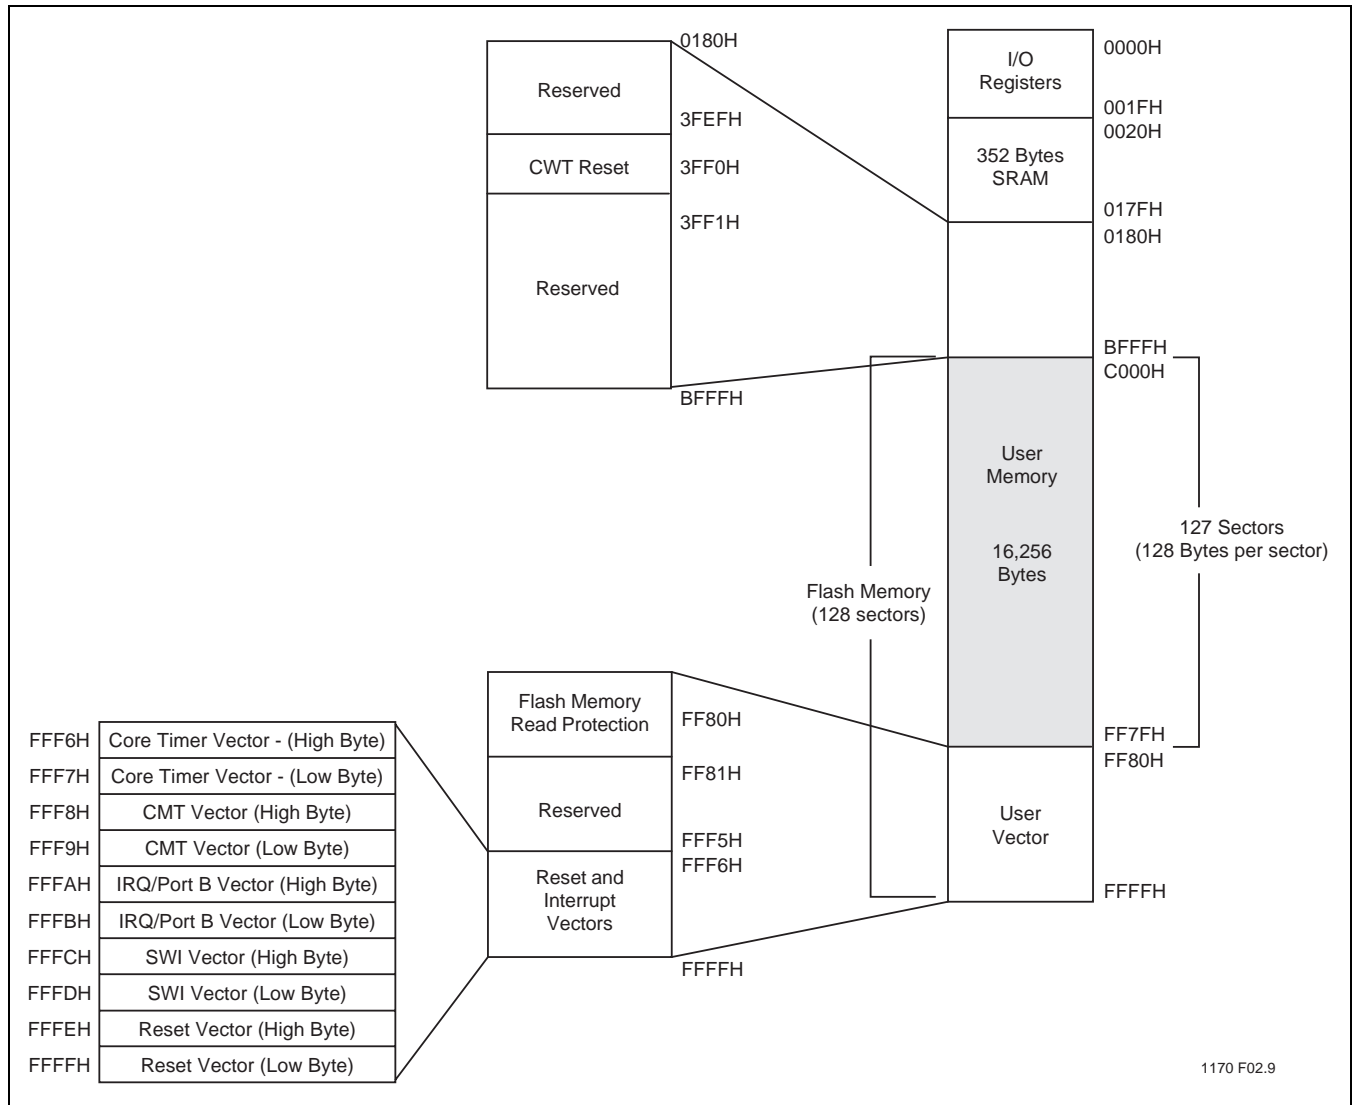

FIGURE   3-1: MEMORY MAP

Data Sheet

3.1 I/O Registers

The 32 Bytes of I/O registers occupy address locations from 0000H to 001FH that include general purpose I/O registers, the SuperFlash Function Register, and on-chip peripheral control registers.

T3-1.8 1170

1. "-" = reserved bits
2. "U" = unaffected by any reset
3. These registers can be reset by either external or internal reset.

Data Sheet

PORT A Data Register (PORTA)

Location	7	6	5	4	3	2	1	0	Reset Value
0000H	PA7	PA6	PA5	PA4	PA3	PA2	PA1	PA0	00H

Symbol	Function
PA[7:0]	Port A data register bit 0 to 7. These bits are for both reading and writing. Write the data to this register will output data to port A pins when it's in output mode. If the pins are set to input mode, only the output data register is updated, port A pins are tri-stated. Reading the data from this register will read the state of port A pins when set in input mode. If the pins are set to output mode, it reads the output data register. See Table 3-2 for details. For a detailed explanation of each parallel I/O port, please refer to Section 4.0, "Parallel Input/Output Ports" on page 20.

PORT B Data Register (PORTB)

Location	7	6	5	4	3	2	1	0	Reset Value
0001H	PB7	PB6	PB5	PB4	PB3	PB2	PB1	PB0	00H

Symbol	Function
PB[7:0]	Port B data register bit 0 to 7. These bits are for both reading and writing. Writing data to this register will output data to port B pins when it's in output mode. If the pins are set to input mode, only the output data register is updated, port B pins are tri-stated. Reading the data from this register will read the state of port B pins when set in input mode. If the pins are set to output mode, it reads the output data register. See Table 3-2 for details.

PORT C Data Register (PORTC)

Location	7	6	5	4	3	2	1	0	Reset Value
0003H	-	-	-	-	DDRC3	DDRC2	DDRC1	DDRC0	00H

Symbol	Function
PC[3:0]	Port C data register bit 0 to 3. These bits are for both reading and writing. Writing data to this register will output data to port C pins when it's in output mode. If the pins are set to input mode, only output data register is updated, port C pins are tri-stated. Reading data from this register will read the state of port C pins when set in input mode. If the pins are set to output mode, it reads the output data register. See Table 3-2 for details.

TABLE 3-2: I/O PIN FUNCTIONS AS GENERAL PURPOSE I/O

Access	DDRA, DDRB, DDRC	Mode	I/O Pin Functions
Write	0	Input	Data is written into the output data register.
Write	1	Output	Data is written into the output data register and output to the I/O pins.
Read	0	Input	The state of I/O is read
Read	1	Output	The output data register is read

T3-2.0 1170

S71170-06-000   7/05

PORT A Data Direction Register (DDRA)

Location	7	6	5	4	3	2	1	0	Reset Value

INPRB[7:0]   Port B interrupt control bits

0: Interrupt is enabled

1: Interrupt is disabled

Data Sheet

PORT B Pull-up Control Register (PBPUC)

Location	7	6	5	4	3	2	1	0	Reset Value
000CH	-	-	-	-	-	-	PU1	PU0	**03H**

Symbol   **Function**

PU1,PU0   Port B pull-up control bits. The following table shows pull-up strength.
Defaults to strong pull-up when reset.

TABLE 3-3: PULL-UP CONTROL BIT DESCRIPTION

PU1	PU0	Pull-up
0	0	No pull-up for Port B bit
0	1	Weak pull-up for each Port B bit
1	0	Weak pull-up for each Port B bit
1	1	Strong pull-up for each Port B bit[1]

T3-3.1 1170

1. Default value after Power-on or Reset

Core Timer Control Status Register (CTCSR)

Location	7	6	5	4	3	2	1	0	Reset Value
0008H	CTOF	RTIF	TOFE	RTIE	TOFC	RTFC	RT1	RT0	**03H**

Symbol	Function
CTOF	Core timer overflow bit. CTOF is a real-only status bit, this bit is set when the 8-bit ripple counter rolls over from FFH to 00H. Writing to this bit has not effect. Reset clears CTOF. CTOF set to zero by writing a one to TOFC.
RTIF	Real-time Interrupt bit. RTIF is a read-only status bit. Writing has no effect on this bit. Reset clears RTIF. The real time interrupt circuit consists of a divider and a one-of-four selector. The input clock frequency that drives the RTI circuit is $E/2^{12}$ with three additional divider stages that allows a maximum interrupt period of 16 ms at the internal peripheral clock rate of 2.048 MHz. 0: Writing a one to RTFC clears the RTIF. 1: When the output of the chosen (one-of-four selector) stage goes active.
TOFE	Timer overflow enable bit. TOFE is statuses bit for both read and write. Reset clears this bit. 0: If the CTOF is not set or no timer overflow occurs. 1: If the CTOF is set and a CPU interrupt request is generated
RTIE	Real time interrupt enable bit. RTIE is a status bit for both read and write. Reset clears this bit. 0: If the RTIF is not set. 1: If the RTIF is set and a CPU interrupt request is generated.
TOFC	Timer overflow flag clear bit. This bit is for writing only. 0: Writing a zero has no effect on the CTOF bit. This bit always reads as zero. 1: When a one is written to this bit, CTOF is cleared.
RTFC	Real time interrupt flag clear bit. This bit is for writing only. 0: Writing a zero has no effect on the RTIF bit. This bit always reads as zero. 1: When a one is written to this bit, RTIF is cleared.
RT[1:0]	Real time interrupt rate select bit. These two bits select one of four taps from the interrupt logic. See Table 3-4. Reset sets these two bits, which selects the lowest periodic rate and gives the maximum. Care should be taken when altering RT0 and RT1 if the timeout period is imminent or uncertain. The CWT should be cleared before changing RTI taps. If the selected tap is modified during a cycle in which the counter is switching, an RTIF could be missed or an additional one could be generated.

TABLE 3-4: RTI AND CWT RATES AT 4.096 MHZ OSCILLATOR, PRESCALER=1

RTI Rate		RT1-RT0	Minimum CWT Rates		Maximum CWT Rates	
2ms	$2^{12}/E^1$	00	$(2^{15}-2^{12})/E$	14ms	$(2^{15})/E$	16ms
4ms	$2^{13}/E$	01	$(2^{16}-2^{13})/E$	28ms	$(2^{16})/E$	32ms
8ms	$2^{14}/E$	10	$(2^{17}-2^{14})/E$	56ms	$(2^{17})/E$	64ms
16ms	$2^{15}/E$	11	$(2^{18}-2^{15})/E$	112ms	$(2^{18})/E$	128ms

T3-4.2 1170

1. E is the internal peripheral clock frequency and $E = F_{OSC}/2$

Core Timer Counter Register (CTCR)

Location	7	6	5	4	3	2	1	0	Reset Value
0009H	CTD7	CTD6	CTD5	CTD4	CTD3	CTD2	CTD1	CTD0	**00H**

Symbol	Function
CTD[7:0]	The core timer counter register bit 0 to bit 7. This is a read only status register in which contains the current value of the 8-bit ripple counter. This counter is clocked by the CPU clock (E/4) and can be used for various functions, including a software input capture. Extended time can be achieved by using the timer overflow function to increment a variable to simulate a 16-bit counter.

SuperFlash Function Register (SFFR)

Location	7	6	5	4	3	2	1	0	Reset Value
000BH	PREN	MEREN	SEREN	-	PROG	MERA	SERA	-	**00H**

Symbol	Function
PREN	Byte program enable bit.
	0: Disable the byte program.
	1: Enable the byte program.
MEREN	Mass (chip) program enable.
	0: Disable the mass (chip) erase or program.
	1: Enable the mass (chip) erase or program.
SEREN	Sector program enable.
	0: Disable the sector erase or program.
	1: Enable the sector erase or program.
PROG	Byte program control bit.
	0: Not performs the byte program
	1: Performs the byte program.
MERA	Mass (chip) program active bit.
	0: Not performs the chip program
	1: Performs the chip program.
SERA	Sector program active bit.
	0: Not performs the sector program.
	1: Performs the sector program.

Therefore, when SFFR=22H, the MCU will perform the Sector-Erase, SFFR=44H, the MCU will perform the Chip-Erase, and SFFR=88H, the MCU will perform the Byte-Program. For a detailed explanation of MCU flash control, please refer to Section 5.1, "In-Application Programming" on page 21.

COP Watchdog Timer Control Register (CWTC)

Location	7	6	5	4	3	2	1	0	Reset Value
000DH	-	-	-	-	-	-	-	CWT_EN	01H

Symbol	Function
CWT_EN	COP watchdog timer enable bit.
	0: COP watchdog timer is enabled.
	1: COP watchdog timer is disabled.

COP Watchdog Timer Reset Register (CWTR)

Location	7	6	5	4	3	2	1	0	Reset Value
3FF0H	-	-	-	-	-	-	-	CWT_CLR	01H

Symbol	Function
CWT_CLR	This bit is for writing only. For detail explanation of COP Watchdog Timer Reset, please refer to Section 6.4
	0: Write zero to this bit will clear COP watchdog timer.
	1: Write one to this bit has no effect. Read this bit will always returns one.

Carrier Generator High Data Register1 (CHR1)

Location	7	6	5	4	3	2	1	0	Reset Value
0010H	IROLN	CMTPOL	PH5	PH4	PH3	PH2	PH1	PH0	00UUUUUUb

Symbol	Function
IROLN	IRO latch control bit. Reading IROLN bit reads the state of the IRO latch. Writing IROLN updates the IRO latch with the data being written on the negative edge of the internal processor clock ($F_{OSC}/2$). The IRO latch is clear out of reset. Writing to CHR1 to update IROLN will also update the primary carrier high data value. In addition, writing to CHR1 to update IROLN will update the CMT polarity bit. Bit 6 should contain the data of CMTPOL polarity bit.
CMTPOL	CMT output polarity bit. This bit controls the polarity of the CMT output (IRO).
	0: the CMT output is active high.
	1: the CMT output is active low.
PH[5:0]	Primary carrier high time data values. When selected, these bits contain the number of input clocks required to generate the carrier high time periods. When operating in timer mode, CHR1 and CLR1 are always selected. When operating in FSK mode, CHR1, CLR1 and CHR2, CLR2 are alternately selected under control of the modulator. The primary carrier high and low time values are undefined on the reset. These bits must be written to non-zero values that before the carrier generator is enabled to avoid spurious results.

Bit 0 to Bit 7 of CHR1 can be used for both reading and writing.

Note:"U" indicates that the bit is unaffected after reset.

Carrier Generator Low Data Register1 (CLR1)

Location	7	6	5	4	3	2	1	0	Reset Value
0011H	IROLP	-	PL5	PL4	PL3	PL2	PL1	PL0	00UUUUUUb

Symbol	Function
IROLP	IRO latch control bit. Reading IROLP bit reads the state of the IRO latch. Writing IROLP updates the IRO latch with the data being written on the negative edge of the internal processor clock ($F_{OSC}/2$). Writing to CLR1 to update IROLP will also update the primary carrier low data value. Care should be taken that bits 5-0 of the data to be written to CHR1 or CLR1.
PL[5:0]	Primary carrier low time data values. The function of these bits is the same as PH[5:0].

Carrier Generator High Data Register2 (CHR2)

Location	7	6	5	4	3	2	1	0	Reset Value
0012H	-	-	SH5	SH4	SH3	SH2	SH1	SH0	00UUUUUUb

Symbol	Function
SH[5:0]	Secondary carrier high time data values. When selected, these bits contain the number of input clocks required to generate the carrier high time periods. When operating in time mode, CHR2 and CLR2 is never selected. When operating in FSK mode, CHR2, CLR2 and CHR1, CLR1 are alternately selected under control of the modulator. The secondary carrier high and low time values are undefined on the reset. These bits must be written to nonzero values before the carrier generator is enabled when operating in FSK mode.

Carrier Generator Low Data Register2 (CLR2)

Location	7	6	5	4	3	2	1	0	Reset Value
0013H	-	-	SL5	SL4	SL3	SL2	SL1	SL0	00UUUUUUb

Symbol	Function
SL[5:0]	Secondary carrier low time data values. The function of these bits is the same as SH[5:0].

Modulator Control and Status Register (MCSR)

Location	7	6	5	4	3	2	1	0	Reset Value
0014H	EOC	DIV2	EIMSK	EXSPC	BASE	MODE	EOCIE	MCGEN	**00H**

Symbol	Function
EOC	End of modulation cycle status bit. This bit is read only. EOC is set when a match occurs between the contents of the space period register SREG and the down counter. At the end of cycle, the counter is initialized with the contents of the mark period buffer, MBUFF and SREG is loaded with the space period buffer SBUFF. This flag is cleared by reading the MCSR followed by an access of MDR2 or MDR3. EOC is cleared by reset. 0: current modulation cycle in progress. 1: end of modulator cycle has occurred.
DIV2	Divide by two scaler bit. The divide-by-two prescaler causes the CMT to be clocked at the bus rate, when the two times of bus rate is enabled and the F_{OSC} is disabled. Since this bit is not double buffered, this bit should not be set during a transmission. 0: divide-by-two prescaler disabled. 1: divide-by-two prescaler enabled.
EIMSK	External Interrupt Mask bit. This bit is used to mask IRQ and keyscan interrupts. This bit is cleared by reset. 0: IRQ and keyscan interrupts enabled. 1: IRQ and keyscan interrupts disabled.
EXSPC	Extended Space Enable bit. For detailed description of extended space operation, please refer to *65P542R Programming User's Manual.* 0: Extended space disabled. 1: Extended space enabled
BASE	Baseband Enable bit. This bit disables the carrier generator and forces the carrier output high for generation of baseband protocols. When BASE is cleared, the carrier generator is enabled and the carrier output toggles at the frequency determined by values stored in the carrier data registers. This bit is cleared by reset. This bit is not double buffered and should not be written during a transmission. 0: Baseband disabled. 1: Baseband enabled.
MODE	Mode select bit. This bit is cleared by reset. This bit is not double buffered and should not be written during a transmission. 0: CMT operates in Time mode. 1: CMT operates in FSK mode.
EOCIE	Interrupt enable bit. Interrupt request will be generated when EOC is set and EOCIE is set. Otherwise, interrupt will not be generated 0: interrupt disabled. 1: interrupt enabled.
MCGEN	Modulator and carrier generator enable bit. Set this bit will initialize the carrier and modulator and will enable all clocks. Once enabled, the carrier generator and modulator will function continuously. 0: if this bit is zero, the current modulator cycle will be allowed to expire before all carrier and modulator clocks are disabled and the modulator output is forced low. To prevent spurious operation, the user should initialize all data and control registers before enabling the system. This bit is cleared by reset. All bits except Bit 0 can be used for both reading and writing. 1: Modulator and carrier generator enabled.

Data Sheet

Modulator Data Register 1 (MDR1)

Location	7	6	5	4	3	2	1	0	Reset Value
0015H	MB11	MB10	MB9	MB8	SB11	SB10	SB9	SB8	UUUUUUUUb

Symbol	Function
MB[11:8]	MBUFF high 4 bits.
SB[11:8]	SBUFF high 4 bits.

These bits can be used for both reading and writing.

Modulator Data Register 2 (MDR2)

0016H	SB7	SB6	SB5	SB4	SB3	SB2	SB1	SB0	UUUUUUUUb

Symbol	Function
SB[7:0]	SBUFF lower 8 bits. The bits can be used for reading and writing.

Power Saving Control Register (PSCR)

Location	7	6	5	4	3	2	1	0	Reset Value
0018H	EN	-	-	-	-	-	STOP	IDL	10000011b

Symbol	Function
EN	This bit enable or disable MCU to stop and idle mode. This bit can be used for both reading and writing. 0: STOP and IDLE mode enable 1: STOP and IDLE mode disable.
STOP	Stop mode enable bit 0: write 0 to this bit will make the device entering the stop mode if EN=0 1: write 1 to this bit has no effect. Read returns one.
IDL	Idle mode enable bit 0: write 0 to this bit will make the device entering the idle mode if EN=0 1: write 1 to this bit has no effect. Read returns one.

3.2 SRAM

There are 352 Bytes of SRAM available. The SRAM addresses start from location 0020H to 017FH. The stack pointer can address 64 Bytes of stack beginning at address location 00FFH and ending at 00C0H.

3.3 SuperFlash Memory

The SST65P542R has 16 KByte of SuperFlash EEPROM memory. The memory is organized as 128 sectors of 128 Bytes each. The minimum erasable memory unit is one sector or 128 Bytes. The user programmable flash memory occupies the address space from C000H to FF7FH. The user vector area consists of 128 Bytes starting from address location FF80H to FFFFH. Address FF80H is for flash memory read protection. There are five predetermined user vectors from FFF6H through FFFFH dedicated to the reset and interrupts. Every vector consists of two bytes to be loaded into program counter for jumping to an interrupt service routine (ISR). See Table 3-5 for detailed descriptions of these vectors.

TABLE 3-5: INTERRUPT/RESET SECTOR

Address Location	User Vectors
FF80H	Flash Memory Read Protection
FF81H-FFF5H	Unused
FFF6H	Core Timer Vector - (High Byte)
FFF7H	Core Timer Vector - (Low Byte)
FFF8H	CMT Vector (High Byte)
FFF9H	CMT Vector (Low Byte)
FFFAH	IRQ/Port B Vector (High Byte)
FFFBH	IRQ/Port B Vector (Low Byte)
FFFCH	SWI Vector (High Byte)
FFFDH	SWI Vector (Low Byte)
FFFEH	Reset Vector (High Byte)
FFFFH	Reset Vector (Low Byte)

T3-5.5 1170

Data Sheet

4.0 PARALLEL INPUT/OUTPUT PORTS

4.1 Port A

Port A consists of eight individual pins driven by one data register and one direction register to control the usage of these pins as either inputs or outputs. All Port A pins are set to Input mode during any Reset. Software must set the right direction register first before performing any Read or Write operation. Any Read operation to the port that was set as output will read back the data from an internal latch register instead of the I/O pins. For details, please refer to Section 3.1 Port A data register and Port A data direction register.

4.2 Port B

Port B pins are similar to Port A pins except that each of the Port B pins has a programmable interrupt generation option which can be enabled for any Port B pins. Port B pins have optional programmable pull-ups. There is a choice between pull-up strengths which could be selected by PU0 or PU1. For details, please refer to Section 3.1, Port B Interrupt Control Register and Port B Pull-up Control Register.

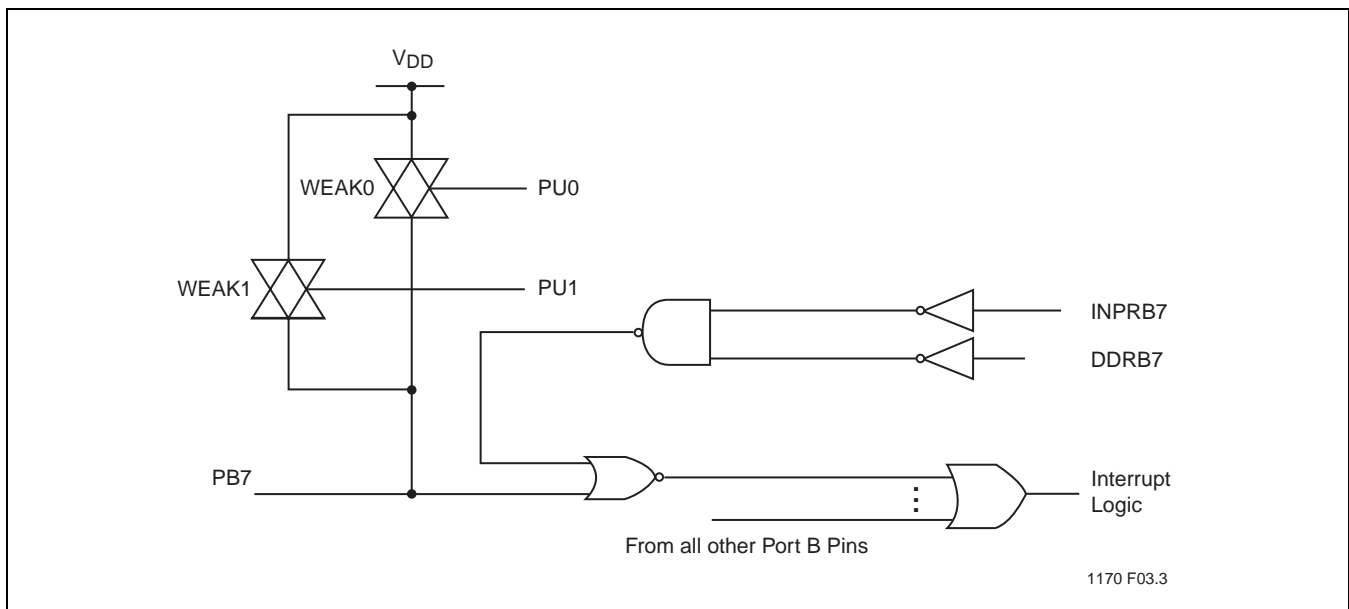

FIGURE   4-1: PORT B INTERRUPT AND PULL-UP OPTIONS

4.3 Port C

Port C is a 4-bit bi-directional port (PC3-PC0). Every Port C pin has high current driving capability. Reset clears the Port C Data Register and the data direction register, thereby returning the ports to inputs. For details, please refer to Section 3.1 Port C data register and Port C data direction register.

5.0 FLASH MEMORY PROGRAMMING

5.1 In-Application Programming

SST65P542R allows "In-Application Programming" (IAP) to update the user code in the internal 16 Kbyte Super-Flash memory. All Write/Erase operations require setting the enable bit in the SuperFlash Function Register (SFFR) located at 000BH. The following sections describe the operations that the MCU performs to alter the contents of SuperFlash Memory. For detailed explanation of the Super-Flash Function Register, please refer to Section 3.1.

5.1.1 Chip-Erase

The Chip-Erase operation requires MEREN and MERA bits to be set to logical "1". After setting these bits, writing any data to any address location of the flash memory will trigger the Chip-Erase operation. The MCU is idle while SST65P542R is busy doing erases on all memory locations.

5.1.2 Sector-Erase

The Sector-Erase operation requires SEREN and SERA bits to be set to logical "1". After setting these bits, writing any data to the address within the sector to be erased will erase the data in the sector. The MCU is idle while SST65P542R is busy doing erase on the sector.

5.1.3 Byte-Program

The Byte-Program operation requires PREN and PROG bits to be set to logical "1". After setting these bits, and then writing the data to the target address to be programmed. The MCU is idle while SST65P542R is busy doing programming on the byte. Refer to the following summary for all different functions.

.
TABLE 5-1: SFFR COMMANDS

Function	Command Writes to SFFR	Comment
Chip-Erase	44H	Erase the whole flash memory
Sector-Erase	22H	Erase the sector addressed by CXXXH
Byte-Program	88H	Program one data byte to address CXXXH. Write data to CXXXH before Byte-Program can be performed, a Chip-Erase or Sector-Erase must be issued to erase the target programming locations.

T5-1.1 1170

5.2 External Host Programming Mode

The external host programming mode is to provide programmer access to the 16KB embedded flash memory of the SST65P542R. To enter the external host programming mode, users must follow the setup sequences on the pins (See Figure 11-1):

1. RY/BY# (pin 12) and POROUT# (pin 13) are output pins. Do not drive.

2. Drive RST# (pin 24) low.

3. Drive LPRST# (pin 21) low.

4. Drive LPRST# (pin 21) high after T_{RST}.

5. Drive PROG_RST (pin 9) low.

6. Drive 9 clocks on TCLKIN. On each clock's rising edge provide one bit of data on TDIN (pin 19) as shown in Figure 11-1. The data bits are "11010011".

7. Wait for RY/BY# (pin 12) and POROUT# to go high.

8. Drive at least 24 clocks on TCLKIN.

9. If Read-protect byte is set, then RY/BY# will go low. Otherwise, RY/BY# will stay high. If RY/BY# is low, wait for RY/BY# (pin 12) to go high. Now the SST65P542R is in external host programming mode and is ready for embedded flash Read or Write operations.

Now the SST65P542R is in the external host programming mode and is ready for embedded flash by the external host Read or Write.

As soon as the RST# is released to '1', chip exits external host programming mode and then enters user mode.

5.2.1 External Host Mode Read Operation

As shown in Figure 11-2, the Read operation needs two address setup cycles and one data setup cycle. The low to high transition on SCLK latches the high order address A[13:8] from the pin AD[5:0] while MODE[1:0] inputs are set to 0H; the low to high transition on SCLK latches the low order address A[7:0] from the pin AD[7:0] while the MODE[1:0] inputs are set to 3H and setting the signal OE# to low; the low to high transition on SCLK latches the data D[7:0] on the pin AD[7:0] while the MODE[1:0] is set to 1H for reading. After reading the data, the external host should set the signal OE# to high.

5.2.2 External Host Mode Write Operation

As shown in Figure 11-3, the Write operation needs two address setup cycles and one data setup cycle. The low to high transition on SCLK latches the high order address A[13:8] from the pin AD[5:0] while the MODE[1:0] inputs are set to 0H; the low to high transition on SCLK latches the low order address A[7:0] from the pin AD[7:0] while MODE[1:0] inputs are set to 2H; the low to high transition on SCLK latches the data D[0:7] from the pin AD[7:0] while the MODE[1:0] is set to 1H for writing. However, the actual Write operation to embedded flash memory occurs on the rising edge of WE#.

TABLE 5-2: EXTERNAL HOST PROGRAMMING MODE PIN DESCRIPTIONS

Pins	Symbol	Type[1]	Name and Functions
8-1	AD[7:0]	I/O[1]	Embedded flash memory address and data bus multiplex on AD[7:0] by selecting MODE[1:0]
10,20	MODE[1:0]	I	Address and data bus selection bits in the external host programming mode
11	SLCK	I	Clock for latch address and data after entering the external host programming mode
9	PROG_RST	I	Reset signal for the external host programming mode
13	POROUT#	O	Embedded flash memory power-on reset output
12	RY/BY#	O	Embedded flash Ready/Busy output. High is ready
17	WE#	I	Write Enable: embedded flash memory data write enable, low active
18	OE#	I	Output Enable: embedded flash memory data out enable, low active
21	LPRST#	I	Signal for entering the external host programming mode
19	TDIN	I	Data input for entering the external host programming mode
23	TCLKIN	I	This clock will latch TDIN for entering the external host programming mode
22	V_{SS}	PWR	Ground: Circuit ground (0V reference)
26	V_{DD}	PWR	Power Supply: Supply voltage (3.2V)

T5-2.3 1170

1. I = Input; O = Output

5.2.3 External Host Mode Byte-Program Operation

This device is programmed on a byte by byte basis. The Byte-Program operation consists of three steps. The first step is the three-byte load sequence for Software Data Protection. The second step is to load the byte address and the byte data. The third step is the internal Program operation which is initiated after the rising edge of the fourth WE#. The end of the Byte-Program operation can be determined by using the RY/BY#. Any commands written during the Byte-Program operation will be ignored. See Table 5-4 for the software command sequence, Figure 11-5 for the flash Byte-Program timing diagram, and Figure 11-9 for the Byte-Program command sequence flowchart.

5.2.4 External Host Mode Chip-Erase Operation.

The device provides a Chip-Erase operation, which allows the user to erase the entire memory array to the '1's state. This is useful when the device must be quickly erased entirely. The Chip-Erase operation is initiated by executing a six-byte Software Data Protection command sequence, the last byte Sequence is the address 1555H with the Chip-Erase command 10H. The Chip-Erase operation begins with of the sixth write enable's (WE#) rising edge. The end of the Chip-Erase can be determined by using the signal RY/BY#. Any commands written during the Chip-Erase operation will be ignored. See Table 5-4 for the software command sequence, Figure 11-4 for the flash Chip-Erase timing diagram, and Figure 11-11 for the Chip-Erase command sequence flowchart.

5.2.5 External Host Mode Sector-Erase Operation

The Sector-Erase operation allows the system to erase the device on a sector-by-sector basis. The sector architecture is based on uniform sector size of 128 Bytes. The Sector-Erase operation is initiated by executing a six-byte command sequence for Software Data Protection, the last byte sequence is the sector address SA with the Sector-Erase command 30H. The address lines A[13:7] will be used to determine the sector address. The internal Erase operation begins after the sixth write enable's (WE#) rising edge. The End-of-Erase can be determined by using the signal RY/BY#. Any commands written during the Sector-Erase operation will be ignored. See Table 5-4 for the software command sequence, Figure 11-5 for the flash Sector-Erase timing diagram, and Figure 11-11 for the Sector-Erase command sequence flowchart.

5.2.6 Operation Status Detection - Program Timer Method

During the Program or Erase operation, the programmer can use the timer to decide the completion of the operation. When a Program or Erase operation is started, system set-up a timer for T_{BP} (for Byte-Program), T_{SCE} (for Chip-Erase), and T_{SE} (for Sector-Erase) time period. After this timer time-out, the operation is completed. See Figure 11-10 for Program Timer flowchart.

5.2.7 Operation Status Detection - RY/BY# Method

During the internal Program or Erase operation, the signal RY/BY# indicates the status of the operation. When the internal Program or Erase operation is in progress, the signal RY/BY# will be driven low. When the internal Program or Erase operation is completed, the signal RY/BY# will be driven high. The device is then ready for the next operation. See Figure 11-10 for the Program Timer flowchart.

5.2.8 Exiting The External Host Programming Mode

To exit the external host programming mode, the external host must set the RST# pin to high, and the PROG_RST is reset to high. The device will exit the host programming and enter the user mode. The MCU starts execution codes out of the User Memory Space from the reset vector.

5.2.9 Flash Read Protection

To protect the program code from piracy the flash memory location 3F80H (user memory address FF80H, flash memory is mapped to C000H through FFFFH, see Figure 3-1) is evaluated by the internal hardware to determine the read protect mode state. During this evaluation period, only the RY/BY# pin is valid and all other pins are blocked. If this byte is A3H (read protect is active), a Chip-Erase will be performed by internal hardware before the external host programming mode is activated. While the Chip-Erase could take T_{SCE} (See Table 11-5) as maximum time, users may use RY/BY# pin to determine the completion of the Chip-Erase. If this byte is not A3H (not read protected), all of the flash memory are visible by using the external host programming. During the internal Program or Erase operation, the signal RY/ BY# indicates the status of the operation. When the internal Program or Erase operation is in progress, the RY/BY# will be driven low. When the internal Program or Erase operation is completed, the RY/BY# will be driven high. The device is then ready for the next operation. See Figure 11-10 for the Program Timer flowchart.

Note: After writing A3H to the flash read protection register, the device needs to continue power-on prior to finishing the programming function. The programming function may include the Program-Verify function.

Data Sheet

6.0 RESET

The 65P542R can be reset from five sources: two external inputs and three internal restart conditions.

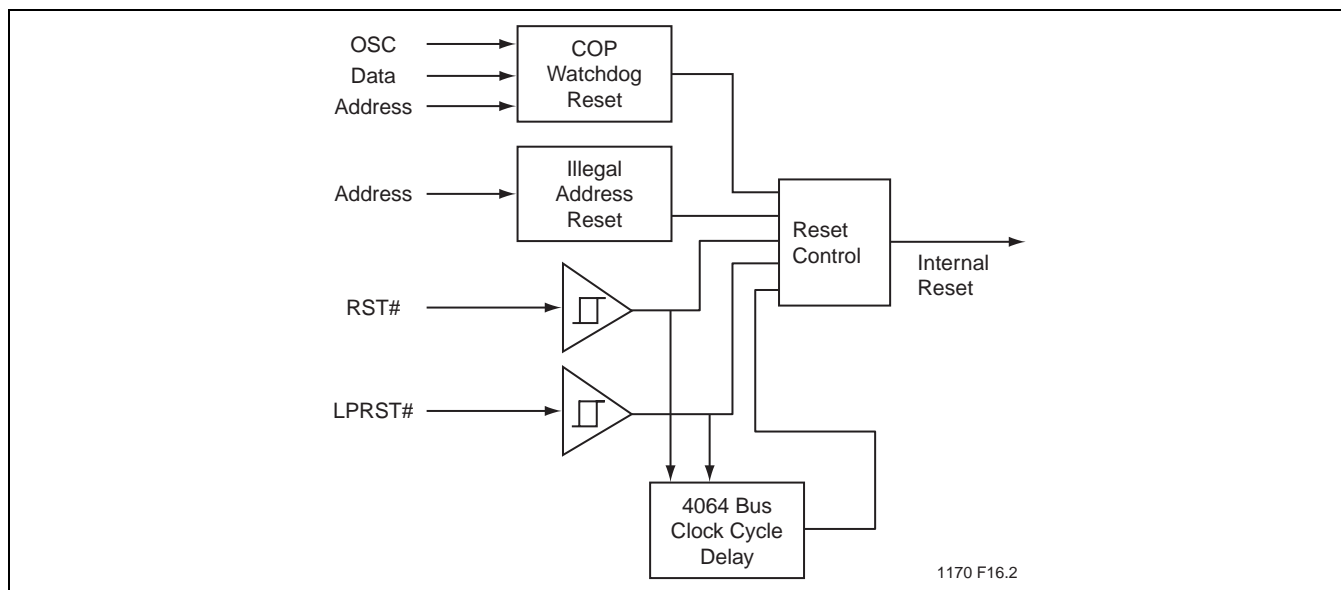

FIGURE 6-1: RESET BLOCK DIAGRAM

6.1 External Reset

A low-level input on the RST# pin causes the program counter to be set to the contents of location FFFEH and FFFFH (Reset Vector). The MCU is initialized to a known state. Stack pointer will be reset to FFH. Hardware Reset is the highest priority input to the chip. An internal Schmitt trigger is implemented on the RST# input to enhance the noise immunity.

6.2 External Low Power Reset

The LPRST# is one of the two external sources of a reset. The signal LPRST# allows the MCU to go into low power reset mode. All clocks and oscillator to the processor are halted when the LPRST# is held low. After the LPRST# is de-asserted (driven high), a delay of 4064 bus clock cycles is automatically enabled to wait for stable crystal oscillation. This pin also implements an internal Schmitt trigger to enhance the noise immunity.

6.3 Internal Power-on and Brown-out Reset

The internal power-on and brown-out reset signal will inhibit flash Erase or Program operations during the power-on or brown-out unstable period to prevent inadvertent Writes to flash memory. The reset signal only affects flash Erase and Program operations. It will not reset other circuits of the device.

During power-up, the internal power-on reset is asserted before V_{DD} reaches V_{POR}. During power-down, the internal brown-out reset is asserted after V_{DD} drops below V_{BOR}. (See Table 11-2)

6.4 COP Watchdog Timer Reset

SST65P542R has a COP (Computer Operating Properly) watchdog timer for monitoring the proper operations of MCU. In normal operation, clearing the COP watchdog timer is executed by software within a preset period of time to avoid reaching time-out condition. To clear the COP watchdog timer, software write "0" to location 3FF0H. The COP Watchdog Reset is asserted and resets the MCU when the time-out condition occurs. The COP watchdog timer is disabled during any external reset. To enable CWT, write logical "0" to CWT control register (000DH). Refer to the *SST65P542R Programming User's Manual* for more information.

6.5 Illegal Address Reset

An illegal address reset is generated when the MCU attempts to fetch an instruction from I/O address space (0000H to 001FH). Those addresses are reserved for I/O registers only.

7.0 INTERRUPTS

SST65P542R accepts five sources of interrupts with highest to lowest priority: Software Interrupt, External Interrupts (IRQ# pin / Port B), CMT Interrupt, and Core Timer Interrupt. Whenever multiple interrupt requests are active at the same time, the higher priority one will be serviced first. All interrupts are maskable except Software Interrupt which is generated by executing SWI instruction. To mask interrupts, set the interrupt mask bit of Process Status Word (PSW). Before serving the interrupt, the MCU registers are pushed onto the stack in the sequence of PCL, PCH, IDX, ACC, PSW. The interrupt service routine should clear the source of interrupt before exiting. By executing RTI instruction, the stored MCU registers are popped from the stack and the program resumes from the interrupted location.

7.1 Software Interrupt

The SWI instruction causes MCU to load the contents of memory locations FFFCH and FFFDH into Program Counter regardless of the interrupt mask bit in PSW register.

7.2 External Interrupts

Upon completion of the current instruction, the MCU responds to the interrupt request that is latched internally. IRQ# must be asserted (low) for at least one T_{ILIH} (125 ns). Following the completion of the current instruction, the interrupt latch is tested. If both interrupt mask bit (I bit) in the PSW is clear and the interrupt request is pending, the interrupt service routine is entered. An external resistor to V_{DD} is required by the IRQ# input for wired-AND operation.

The external interrupts, IRQ# pin and Port B interrupts are edge-sensitive and asserted on the falling edge of the pins. The Port B Interrupt Control Register enables or disables interrupts on each individual pin of port B. The External Interrupt Mask Bit (EIMSK) of Modulator Control and Status register can be used to mask all external interrupts so that lower priority interrupts such as timer interrupts can be served. The state of any external interrupt received during the masked period is preserved. When the EIMSK bit is clear, the pending interrupts activate the MCU interrupt processing again. The external interrupt causes MCU to load the contents of memory locations FFFAH and FFFBH into the Program Counter.

7.3 CMT Interrupt

A CMT interrupt is generated when the end of cycle flag (EOC) and the end of cycle interrupt enable (EOCIE) bits are set in the modulator control and status register (MCSR). This interrupt will vector to the interrupt service routine located at the address specified by the contents of memory locations FFF8H and FFF9H.

7.4 Core Timer Interrupt

The core timer is a 14-stage multifunctional ripple timer. User can select overflow or real-time interrupt by the setting of the Core Timer Control Status Register. Please see the timer section for more details. The timer interrupt causes MCU to load the contents of memory locations FFF6H and FFF7H into the Program Counter.

Data Sheet

8.0 OPERATION MODES

The device can operate in two different modes. The Operation mode includes the User mode and the Learning mode. The pin definitions vary between different operation modes as described in Table 8-1.

8.1 User Mode

In the user mode, the embedded MCU fetches program codes from the user memory space. Please refer to the *SST65P542R Programming User's Manual* for instruction sets and the internal MCU programming information.

8.2 Learning Mode

To enter the learning mode, input the IR signal to the IRQ# pin, then use the BIL and BIH instruction set to record the input signal width. For detail information on learning mode, please refer to the application note *Remote Controller Learning Algorithm using SST65P542R*.

TABLE   8-1: PIN ASSIGNMENT FOR DIFFERENT OPERATION MODES

Pin #[1]	Normal Interface Modes		External Host Programming Mode[1]

27	OSC2	OSC2	Do not use[2]
28	OSC1	OSC1	V_{IL}

T8-1.8 1170

1. See Table 5-2 for pin description.
2. OSC2 is an output, not used during external host program mode.

9.0 PERIPHERALS AND OTHERS

9.1 Core Timer

Core Timer provides the following features:

1. Real Time Interrupt (RTI)

2. Timer Overflow

3. COP watchdog timer

4. Power-on reset (POR)

Please refer to *SST65P542R Programming User's Manual* for programming information.

9.2 Carrier Modulator Transmitter (CMT)

SST65P542R integrates a carrier modulator transmitter for supporting various encoding methods. The purpose of this module is to reduce the loading of the MCU. Three major functions are performed by this block: carrier generation, modulation, and transmission.

Please refer to *SST65P542R Programming User's Manual* for programming information.

9.3 Clock Input Options

Control connections for the 2-lead on-chip oscillator are the OSC1 and OSC2 pins. OSC1 is input and OSC2 is output. A crystal resonator, ceramic resonator, or external clock signal can drive the oscillator.

9.4 Crystal/Ceramic Resonator

A crystal/ceramic oscillator circuit is shown in Figure 9-1. A ceramic resonator instead of a crystal may be used to reduce costs. It is recommended that the resonator and capacitors be mounted as close to the pins as possible to minimize output distortion.

Crystal manufacturer, supply voltage, and other factors may cause circuit performance to differ from one application to another. C1 and C2 should be adjusted appropriately for each design.

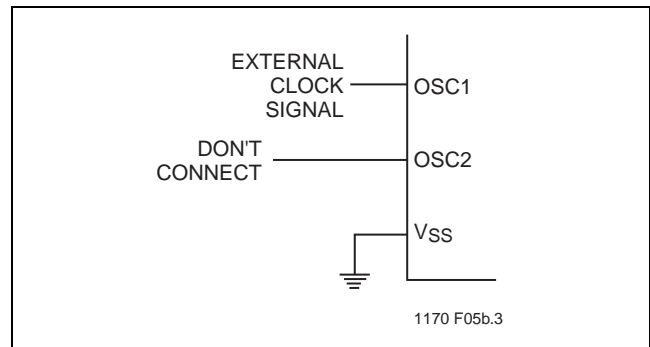

FIGURE   9-1: USING THE CRYSTAL

FIGURE   9-2: EXTERNAL CLOCK DRIVE

9.5 External Clock Drive

If external clock source is provided, OSC1 is the clock input and OSC2 is don't connect. Leave OSC2 open.

10.0 POWER SAVING MODES

SST65P542R provides two power saving modes: Stop mode and Idle mode. These two modes can be entered through the setting of the Power Saving Control Register. Refer to Section 3.1 for power saving control register.

10.1 STOP Mode

Writing a logic '0' to the STOP bit of the Power Saving Control Register enters the STOP mode. To achieve the lowest possible power consumption, the implementation uses STOP bit to gate off the internal clock. See Figure 10-1 for illustration of clock arrangement in the STOP mode. Since there is no clock input, the internal states are maintained and not changed including I/O registers and RAM memory except that the core timer counter bits are cleared. The external IRQ interrupt can brought the device out of the STOP mode, but all other interrupts are not served until the device is recovered from STOP mode. There are three conditions that will recover the device from the STOP mode: external IRQ#/Port B interrupt (EIMSK=0), RST# or external reset LPRST#. The STOP bit will be set to 1 when the device has been brought out of STOP mode. The interrupt mask bit (I bit) will not be affected.

10.2 IDLE Mode

Writing a logic '0' to the IDLE bit of the Power Saving Control Register enters the IDLE mode. In the IDLE mode, the timer is still running. Any internal or external interrupt will recover the device from IDLE mode. If both STOP and IDLE bits are '0', then STOP mode takes effect. The IDLE bit will be set to 1 when the device has been brought out of the IDLE mode. The interrupt mask bit (I bit) will not be affected.

FIGURE 10-1: STOP MODE AND IDLE MODE

11.0 ELECTRICAL SPECIFICATION

11.1 Absolute Maximum Stress Ratings

Absolute Maximum Stress Ratings (Applied conditions greater than those listed under "Absolute Maximum Stress Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these conditions or conditions greater than those defined in the operational sections of this data sheet is not implied. Exposure to absolute maximum stress rating conditions may affect device reliability.)

Ambient Temperature Under Bias . . . . -55°C to +125 °C

Storage Temperature . . . . -65 °C to + 150 °C

DC Voltage on Any Pin to Ground Potential. . . . . -0.5V to V_{DD}+0.5V

Transient Voltage (<20 ns) on any Pin to Ground Potential . . . . -1.0V to V_{DD}+1.0V

Package Power Dissipation Capability (T_A = 25 °C). 1.0W

Surface Mount Solder Reflow Temperature[1] . . . . 260°C for 10 seconds

Output Short Circuit Current[2]. . . . . 100 mA

1. Excluding certain with-Pb 32-PLCC units, all packages are 260°C capable in both non-Pb and with-Pb solder versions. Certain with-Pb 32-PLCC package types are capable of 240°C for 10 seconds; please consult the factory for the latest information.
2. Outputs shorted for no more than one second. No more than one output shorted at a time. (Based on package heat transfer limitations, not devices power consumption.)

11.2 Reliability Characteristics

TABLE   11-1: RELIABILITY CHARACTERISTICS

Symbol	Parameter	Minimum Specification	Units	Test Method
N_{END}	Endurance	10,000	Cycles	JEDEC Standard A117
T_{DR}[1]	Data Retention	100	Years	JEDEC Standard A103
I_{LTH}[1]	Latch Up	100+I_{DD}	mA	JEDEC Standard 78

T11-1.3 1170

1. The parameter is measured only for initial qualification and after a design or process change that could affect this parameter.

11.3 DC Specifications

TABLE   11-2: RECOMMENDED DC OPERATING CONDITIONS (T_A= 0°C to +70°C)

Symbol	Parameter	Min	Max	Unit
V_{DD}	Supply Voltage	2.2	3.2	V
T_A	Temperature	0	+70	°C
F_{OSC}	Osc. Frequency	0	8	MHz
V_{POR}[1]	Power-on Reset	2.0	2.2	V
V_{BOR}[1]	Brown-out Reset	1.9	2.1	V

T11-2.2 1170

1. Power-on reset and Brown-out reset only affect flash Erase and Program operations. To avoid indeterministic MCU behavior and prevent inadvertent flash memory corruption, when supply voltage dips below VDD min, an external low voltage detection circuitry is required to generate reset signal to the chip. The trip point for this circuitry should be set at 2.2V±5%.

Data Sheet

11.4 DC Electrical Characteristics

TABLE   11-3: DC ELECTRICAL CHARACTERISTICS (T_A = 0°C to +70°C, V_{DD} = 2.2-3.2V, V_{SS} = 0V)

Symbol	Parameter	Min	Max	Typ	Unit
I_{DD}[1]	**Supply Current**				
	Run without Flash Erase/Program Operation	-	8	2.5	mA
	Run with Flash Erase/Program Operation	-	20	10	mA
	Idle[2]		2.75	0.8	mA
	Stop				
	25°		6	4	µA
	0°to +70°		15	9	µA
I_{OZ}	**I/O Ports Hi-Z Leakage current**				
	Port A, Port B, Port C	-10	10	-	µA
I_{IN}	**Input Current**				
	IRQL, RESETL, LPRSTL, OSC1	-1	1	-	µA
	Port B with Strong Pull-ups Enable (V_{IN} = 0.2xV_{DD})	-34	-74	-50	
	Port B with Strong Pull-ups Enabled (V_{IN} = 0.8xV_{DD})	-15	-36	-25	
	Port B with Weak Pull-ups Enable (V_{IN} = 0.2xV_{DD})	-17	-37	-25	
	Port B with Weak Pull-ups Enabled (V_{IN} = 0.8xV_{DD})	-7.5	-18	-12.5	
	Output Voltage				
V_{OL}	(I_{LOAD} = 1 mA) OSC2	-	0.4	-	µA
V_{OH}	(I_{LOAD} = -500 µA) OSC2	V_{DD}-0.4	-	-	
V_{OH}	**Output High Voltage**				
	(I_{LOAD} = -1.2 mA) Port A, Port B	V_{DD}-0.4		V_{DD}-0.3	V
	(I_{LOAD} = -6 mA) IRO	V_{DD}-0.8		V_{DD}-0.3	
	(I_{LOAD} = -4 mA) Port C	V_{DD}-0.5		V_{DD}-0.3	
V_{OL}	**Output Low Voltage**				
	(I_{LOAD} = 1.8 mA) Port A, Port B		0.4	0.2	V
	(I_{LOAD} = 12 mA) IRO		0.8	0.3	
	(I_{LOAD} = 8 mA) Port C		0.5	0.3	
V_{IH}	**Input High Voltage**				
	Port A, Port B, Port C, OSC1	0.8 V_{DD}	V_{DD}	-	V
	IRQL, RESETL, LPRSTL	0.8 V_{DD}	V_{DD}	-	
V_{IL}	**Input Low Voltage**				
	Port A, Port B, Port C, OSC1	V_{SS}	0.2 V_{DD}	-	V
	IRQL, RESETL, LPRSTL	V_{SS}	0.2 V_{DD}	-	

T11-3.4 1170

1. Test conditions for I_{DD} are 8 MHz and 20 pf loading.
2. Idle current I_{DD} is 0.4 mA typical, 0.6 mA maximum at 4 MHz, 2.2V, and 20 pf loading.

11.5 AC Electrical Characteristics

TABLE 11-4: CONTROL TIMING (T_A = 0°C to +70°C, V_{DD} = 2.2 to 3.2V, V_{SS} = 0V)

Symbol	Characteristic	Min	Max	Unit
	Frequency of operation			
F_{OSC}	Crystal		8	MHz
F_{EXT}	External clock		8	MHz
F_{OP}	Internal Operating Frequency		4	MHz
T_{CYC}	Cycle Time	125		ns
T_{OXOV}[1]	Crystal Oscillator Startup Time		100	ms
T_{ILCH}[1]	Stop Recovery Startup Time		100	ms
T_{RL}[1]	RST# Pulse Width	1.5		T_{CYC}
T_{ILIH}[1]	Interrupt Pulse Width Low (Edge-Triggered)	125		ns
T_{OH},T_{OL}[1]	OSC1 Pulse Width	90		ns

T11-4.2 1170

1. Guaranteed by design.

TABLE 11-5: EXTERNAL HOST PROGRAMMING-MODE TIMING PARAMETERS

Symbol	Parameter	Min	Max	Units
T_{AS}[1]	Address/Data Setup Time	30		ns
T_{CP}[1]	SCLK Cycle Time	130		ns
T_{AH}[1]	Address/Data Hold Time	45		ns
T_{CPH}[1]	SCLK Pulse Width High	65		ns
T_{SE}	Sector-Erase Time[2]		25	ms
T_{SCE}	Chip-Erase Time[2]		120	ms
T_{BP}	Byte-Program Time[2]		80	μs
T_{DH}[1]	TDIN Hold Time	45		ns
T_{DS}[1]	TDIN Setup Time	30		ns
T_{DP}[1]	TCLKIN Pulse Width	65		ns
T_{DPH}[1]	TCLKIN Pulse Width High	65		ns
T_{RST}[1]	Reset Time	720		ns

SST65   P   5 4   2   R - 8 -   C - SG E
SSTXX   X   X X   X   X - X -   X - XX X

Environmental Attribute
E[1] = non-Pb

Package Modifier
G = 28 leads

Package Type
S = SOIC

Operation Temperature
C = Commercial: 0°C to +70°C

Operating Frequency
8 = 8.0 MHz

Function
R = Remote Controller

On-Chip SRAM Size
2 = 352 Bytes

Flash Memory Size
4 = 16 KByte

Core Sub-Block
5 = Enhanced 6502 core

Voltage
2.2- 3.2V

Product Series

1. Environmental suffix "E" denotes non-Pb solder.
   SST non-Pb solder devices are "RoHS Compliant".

12.1 Valid Combinations
Valid combinations for SST65P542R

SST65P542R-8-C-SG   SST65P542R-8-C-SGE

Note: Valid combinations are those products in mass production or will be in mass production. Consult your SST sales representative to confirm availability of valid combinations and to determine availability of new combinations.
