

**PRoC™ LP Features**

- USB 2.0-USB-IF certified (TID # 40000552)
- Single Device, Two Functions
  - 8-bit, Flash based USB peripheral MCU function and 2.4 GHz radio transceiver function in a single device
- Flash-based Microcontroller Function
  - M8C based 8-bit CPU, optimized for Human Interface Devices (HID) applications
  - 256 Bytes of SRAM
  - 8 Kbytes of Flash memory with EEPROM emulation
  - In-System reprogrammable through D+/D- pins.
  - 16-bit free running timer
  - Low power wake up timer
  - 12-bit Programmable Interval Timer with interrupts
  - Watchdog timer
- Industry-Leading 2.4 GHz Radio Transceiver Function
  - Operates in the unlicensed worldwide Industrial, Scientific and Medical (ISM) band (2.4 GHz–2.483 GHz)
  - DSSS data rates of up to 250 Kbps
  - GFSK data rate of 1 Mbps
  - -97 dBm receive sensitivity
  - Programmable output power of up to +4 dBm
  - Auto Transaction Sequencer (ATS)
  - Framing CRC and Auto ACK
  - Received Signal Strength Indication (RSSI)
  - Automatic Gain Control (AGC)
- Component Reduction
  - Integrated 3.3V regulator
  - Integrated pull up on D-
  - GPIOs that require no external components
  - Operates off a single crystal
- Flexible IO
  - 2mA source current on all GPIO pins. Configurable 8-mA or 50-mA/pin current sink on designated pins
  - Each GPIO pin supports high-impedance inputs, configurable pull up, open-drain output, CMOS/TTL inputs and CMOS output
  - Maskable interrupts on all IO pins
- USB Specification Compliance
  - Conforms to USB Specification Version 2.0
  - Conforms to USB HID Specification Version 1.1
  - Supports one Low Speed USB device address
  - Supports one control endpoint and two data endpoints
  - Integrated USB Transceiver
- Operating voltage from 4.0V to 5.5V DC
- Operating temperature from 0 to 70°C
- Pb-Free 40-lead QFN package
- Advanced development tools based on Cypress's PSoC® Tools

## Applications

The CYRF69213 PRoC LP Low Speed is targeted for the following applications:

- USB Bridge for Human Interface Devices (HID)
  - Wireless mice
  - Wireless keyboards
  - Remote controls
  - Gaming applications
- USB Bridge for General Purpose Applications
  - Consumer electronics
  - Industrial applications
  - White goods
  - Home automation
  - Personal health

## Functional Description

PRoC LP devices are integrated radio and microcontroller functions in the same package to provide a dual-role single-chip solution.

Communication between the microcontroller and the radio is via the SPI interface between both functions.

## Functional Overview

The CYRF69213 is a complete Radio System-on-Chip device, providing a complete RF system solution with a single device and a few discrete components. The CYRF69213 is designed to implement low-cost wireless systems operating in the worldwide 2.4-GHz Industrial, Scientific, and Medical (ISM) frequency band (2.400 GHz–2.4835 GHz).

### 2.4 GHz Radio Function

The radio meets the following world-wide regulatory requirements:

- Europe
  - ETSI EN 301 489-1 V1.4.1
  - ETSI EN 300 328-1 V1.3.1
- North America
  - FCC CFR 47 Part 15

- Japan
  - ARIB STD-T66

### Data Transmission Modes

The radio supports four different data transmission modes:

- In GFSK mode, data is transmitted at 1 Mbps without any DSSS
- In 8DR mode, 1 byte is encoded in each PN code symbol transmitted
- In DDR mode, 2 bits are encoded in each PN code symbol transmitted
- In SDR mode, a single bit is encoded in each PN code symbol transmitted

Both 64-chip and 32-chip data PN codes are supported. The four data transmission modes apply to the data after the Start of Packet (SOP). In particular, the packet length, data and CRC are all sent in the same mode.

### USB Microcontroller Function

The microcontroller function is based on the powerful CYRF69213 microcontroller. It is an 8-bit Flash programmable microcontroller with integrated low speed USB interface.

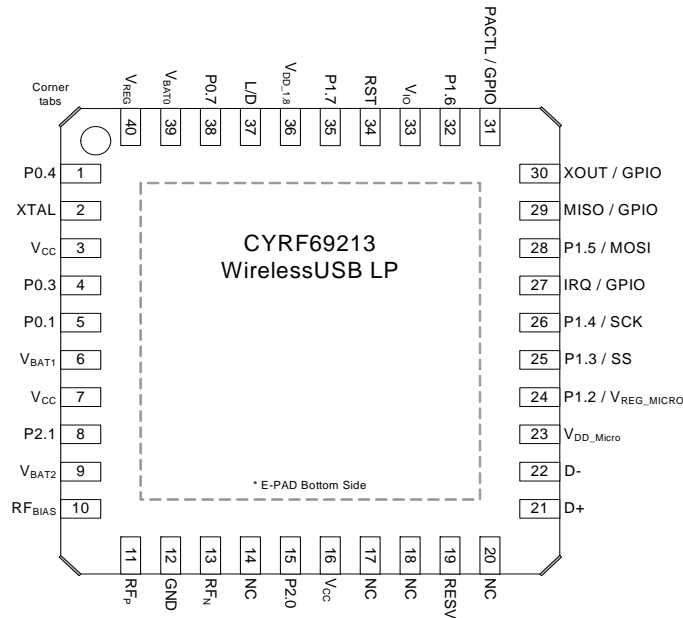

The microcontroller has up to 14 GPIO pins to support USB, PS/2 and other applications. Each GPIO port supports high-impedance inputs, configurable pull up, open drain output, CMOS/TTL inputs and CMOS output. Up to two pins support programmable drive strength of up to 50 mA. Additionally each IO pin can be used to generate a GPIO interrupt to the microcontroller. Each GPIO port has its own GPIO interrupt vector with the exception of GPIO Port 0.

The microcontroller features an internal oscillator. With the presence of USB traffic, the internal oscillator can be set to precisely tune to USB timing requirements (24 MHz ± 1.5%).

The PRoC LP has up to 8 Kbytes of Flash for user's firmware code and up to 256 bytes of RAM for stack space and user variables.

The PRoC LP includes a Watchdog timer, a vectored interrupt controller, a 12-bit programmable interval timer with configurable 1-ms interrupt and a 16-bit free running timer with capture registers.

Figure 1. Pinout Diagram - 40-Lead QFN 7 x 7 mm LF48A

Pin configuration

| Pin                | Name                    | Function  |
|--------------------|-------------------------|---|
| 1                  | P0.4                    | Individually configured GPIO  |
| 2                  | Xtal_in                 | 12 MHz Crystal. External Clock in   |
| 3, 7, 16           | V <sub>CC</sub>         | Connected to pin 24 via 0.047-μF Capacitor.                               |
| 4                  | P0.3                    | Individually configured GPIO  |
| 5                  | P0.1                    | Individually configured GPIO  |
| 6, 9, 39           | V <sub>bat</sub>        | Connected to pin 24 via 0.047-μFshunt capacitor                           |
| 8                  | P2.1                    | GPIO. Port 2 Bit 1  |
| 10                 | RF Bias                 | RF pin voltage reference  |
| 11                 | RF <sub>p</sub>         | Differential RF input to/from antenna                                     |
| 12                 | GND                     | Ground  |
| 13                 | RF <sub>n</sub>         | Differential RF to/from antenna   |
| 14, 17, 18, 20, 36 | NC                      |   |
| 15                 | P2.0                    | GPIO. Port 2 Bit 0  |
| 19                 | RESV                    | Reserved. Must connect to GND   |
| 21                 | D+                      | Low-speed USB IO  |
| 22                 | D-                      | Low-speed USB IO  |
| 23                 | V <sub>DD_micro</sub>   | 4.0–5.5 for 12 MHz CPU/4.75–5.5 for 24 MHz CPU                            |
| 24                 | P1.2 / V <sub>REG</sub> | Must be configured as 3.3V output. It must have a 1–2 μF output capacitor |
| 25                 | P1.3 / nSS              | Slave select SPI Pin  |
| 26                 | P1.4 / SCK              | Serial Clock Pin from MCU function to radio function                      |
| 27                 | IRQ                     | Interrupt output, configure high/low or GPIO                              |
| 28                 | P1.5 / MOSI             | Master Out Slave In.  |
| 29                 | MISO                    | Master In Slave Out, from radio function.Can be configured as GPIO        |
| 30                 | XOUT                    | Bufferd CLK, PACTL_n or GPIO  |

**Pin configuration** (continued)

| Pin | Name                | Function  |
|-----|---------------------|---|
| 31  | PACTL               | Control for external PA or GPIO   |
| 32  | P1.6                | GPIO. Port 1 Bit 6  |
| 33  | V <sub>IO</sub>     | IO interface voltage. Connected to pin 24 via 0.047 $\mu$ F   |
| 34  | Reset               | Radio Reset. Connected to V <sub>DD</sub> via 0.47 $\mu$ F Capacitor or to microcontroller GPIO pin. Must have a RESET = HIGH event the very first time power is applied to the radio otherwise the state of the radio function control registers is unknown. |
| 35  | P1.7                | GPIO. Port 1 Bit 7  |
| 36  | V <sub>DD_1.8</sub> | Regulated logic bypass. Connected via 0.47 $\mu$ F to GND   |
| 37  | L/D                 | Connected to GND  |
| 38  | P0.7                | GPIO. Port 0 Bit 7  |
| 40  | V <sub>reg</sub>    | Connected to pin 24   |
| 41  | E-pad               | Must be connected to GND  |
| 42  | Corner Tabs         | Do not connect corner tabs  |

**PRoC LP Functional Overview**

The SoC is designed to implement wireless device links operating in the worldwide 2.4-GHz ISM frequency band. It is intended for systems compliant with world-wide regulations covered by ETSI EN 301 489-1 V1.41, ETSI EN 300 328-1 V1.3.1 (Europe), FCC CFR 47 Part 15 (USA and Industry Canada) and TELEC ARIB\_T66\_March, 2003 (Japan).

The SoC contains a 2.4-GHz 1-Mbps GFSK radio transceiver, packet data buffering, packet framer, DSSS baseband controller, Received Signal Strength Indication (RSSI), and SPI interface for data transfer and device configuration.

The radio supports 98 discrete 1-MHz channels (regulations may limit the use of some of these channels in certain jurisdictions). In DSSS modes the baseband performs DSSS spreading/despreading, while in GFSK Mode (1 Mb/s - GFSK) the baseband performs Start of Frame (SOF), End of Frame (EOF) detection and CRC16 generation and checking. The baseband may also be configured to automatically transmit Acknowledge (ACK) handshake packets whenever a valid packet is received.

When in receive mode, with packet framing enabled, the device is always ready to receive data transmitted at any of the supported bit rates, except SDR, enabling the implementation of mixed-rate systems in which different devices use different data rates. This also enables the implementation of dynamic data rate systems, which use high data rates at shorter distances and/or in a low-moderate interference environment, and change to lower data rates at longer distances and/or in high interference environments.

The MCU function is an 8-bit Flash-programmable microcontroller with integrated low-speed USB interface. The instruction set has been optimized specifically for USB operations, although it can be used for a variety of other embedded applications.

The MCU function has up to eight Kbytes of Flash for user's code and up to 256 bytes of RAM for stack space and user variables.

In addition, the MCU function includes a Watchdog timer, a vectored interrupt controller, a 16-bit Free-Running Timer, and 12-bit Programmable Interrupt Timer.

The MCU function supports in-system programming by using the D+ and D- pins as the serial programming mode interface. The programming protocol is not USB.

**Backward Compatibility**

The CYRF69213 IC is fully interoperable with the main modes of other Cypress radios CYWUSB6934 and CYRF6936. The 62.5-kbps mode is supported by selecting 32-chip DATA\_CODE\_ADR codes, DDR mode, and disabling the SOP, length, and CRC16 fields.

Similarly, the 15.675-kHz mode is supported by selecting 64-chip DATA\_CODE\_ADR codes and SDR mode. In this way, a suitably configured CYRF69213 IC device may transmit data to and/or receive data from a first generation device. Backwards compatibility requires disabling the SOP, length, and CRC16 fields.

Shown below are the different configurations of the registers and firmware that enable a new generation radio to communicate with a first generation radio. There are two possible modes: SDR and DDR mode (8-DR and GFSK modes are not present in the first generation radio). The second generation radio must be initialized using the RadiolnitAPI of the LP radio driver and then the following registers' bits need to be configured to the given Byte values. Essentially, the following deactivates the added features of the second generation radio and takes it down to the level of the first generation radio; the data format, data rates, and the PN codes used are

**DDR MODE**
**Table 1. DDR Mode**

| REGISTER         | VALUE    | DESCRIPTION  |
|------------------|----------|--|
| TX_CFG_ADR       | 0X16     | 32 chip PN Code, DDR, PA = 6   |
| RX_CFG_ADR       | 0X4B     | AGC is enabled. LNA and attenuator are disabled. Fast turn around is disabled, the device uses high side receive injection and Hi-Lo is disabled. Overwrite to receive buffer is enabled and the RX buffer is configured to receive eight bytes maximum.                           |
| XACT_CFG_ADR     | 0X05     | AutoACK is disabled. Forcing end state is disabled. The device is configured to transition to Idle mode after a Receive or Transmit. ACK timeout is set to 128 $\mu$ s.  |
| FRAMING_CFG_ADR  | 0X00     | All SOP and framing features are disabled. Disable LEN_EN=0 if EOP is needed.  |
| TX_OVERRIDE_ADR  | 0X04     | Disable Transmit CRC-16.   |
| RX_OVERRIDE_ADR  | 0X14     | The receiver rejects packets with a zero seed. The Rx CRC-16 Checker is disabled and the receiver accepts bad packets that do not match the seed in CRC_seed registers. Basically this helps in communication with the first generation radio that does not have CRC capabilities. |
| ANALOG_CTRL_ADR  | 0X01     | Set ALL SLOW. When set, the synthesizer settle time for all channels is the same as the slow channels in the first generation radio.   |
| DATA32_THOLD_ADR | 0X03     | Sets the number of allowed corrupted bits to 3.  |
| EOP_CTRL_ADR     | 0x01     | Sets the number of consecutive symbols for non-correlation to detect end of packet.  |
| PREAMBLE_ADR     | 0xAAAA05 | AAAA are the two preamble bytes. Other Bytes can also be written into the preamble register file. The number of preamble bytes to be sent should be >4.  |

**SDR MODE**
**Table 2. SDR Mode**

| REGISTER         | VALUE    | DESCRIPTION   |
|------------------|----------|---|
| TX_CFG_ADR       | 0X3E     | 64 chip PN code, SDR mode, PA = 6.  |
| RX_CFG_ADR       | 0X4B     | AGC is enabled. LNA and attenuator are disabled. Fast turn around is disabled, the device uses high side receive injection and Hi-Lo is disabled. Overwrite to receive buffer is enabled and RX buffer is configured to receive eight bytes maximum. Enables RXOW to allow new packets to be loaded into the receive buffer. This also enables the VALID bit which is used by the first generation radio's error correction firmware. |
| XACT_CFG_ADR     | 0X05     | AutoACK is disabled. Forcing end state is disabled. The device is configured to transition to Idle mode after Receive or Transmit. ACK timeout is set to 128 $\mu$ s.   |
| FRAMING_CFG_ADR  | 0X00     | All SOP and framing features are disabled. Disable LEN_EN=0 if EOP is needed.   |
| TX_OVERRIDE_ADR  | 0X04     | Disable Transmit CRC-16.  |
| RX_OVERRIDE_ADR  | 0X14     | The receiver rejects packets with a zero seed. The RX CRC-16 checker is disabled and the receiver accepts bad packets that do not match the seed in the CRC_seed registers. Basically this helps in communication with the first generation radio that does not have CRC capabilities.  |
| ANALOG_CTRL_ADR  | 0X01     | Set ALL SLOW. When set, the synthesizer settle time for all channels is the same as the slow channels in the first generation radio, for manual ACK consistency   |
| DATA64_THOLD_ADR | 0X07     | Sets the number of allowed corrupted bits to 7 which is close to the recommended 12% value.   |
| EOP_CTRL_ADR     | 0xA1     | Sets the number of consecutive symbols for non-correlation to detect end of packet.   |
| PREAMBLE_ADR     | 0xAAAA09 | AAAA are the two preamble bytes. Any other byte can also be written into the preamble register file. The number of preamble bytes to be sent should be >8.  |

## Functional Block Overview

All the blocks that make up the PRoC LP are presented here.

### 2.4-GHz Radio

The radio transceiver is a dual conversion low IF architecture optimized for power and range/robustness. The radio employs channel-matched filters to achieve high performance in the presence of interference. An integrated Power Amplifier (PA) provides up to +4 dBm transmit power, with an output power control range of 34 dB in 7 steps. The supply current of the device is reduced as the RF output power is reduced.

**Table 3. Internal PA Output Power Step Table**

| PA Setting | Typical Output Power (dBm) |
|------------|----------------------------|
| 7          | +4                         |
| 6          | 0                          |
| 5          | -5                         |
| 4          | -10                        |
| 3          | -15                        |
| 2          | -20                        |
| 1          | -25                        |
| 0          | -30                        |

### Frequency Synthesizer

Before transmission or reception may commence, it is necessary for the frequency synthesizer to settle. The settling time varies depending on channel; 25 fast channels are provided with a maximum settling time of 100 μs.

The ‘fast channels’ (<100-μs settling time) are every third frequency, starting at 2400 MHz up to and including 2472 MHz (for example, 0,3,6,9.....69 & 72).

### Baseband and Framer

The baseband and framer blocks provide the DSSS encoding and decoding, SOP generation and reception and CRC16 generation and checking, as well as EOP detection and length field.

#### Data Rates and Data Transmission Modes

The SoC supports four different data transmission modes:

- In GFSK mode, data is transmitted at 1 Mbps, without any DSSS.
- In 8DR mode, 8 bits are encoded in each DATA\_CODE\_ADR derived code symbol transmitted.
- In DDR mode, 2-bits are encoded in each DATA\_CODE\_ADR derived code symbol transmitted. (As in the CYWUSB6934 DDR mode).
- In SDR mode, 1 bit is encoded in each DATA\_CODE\_ADR derived code symbol transmitted. (As in the CYWUSB6934 standard modes.)

Both 64-chip and 32-chip DATA\_CODE\_ADR codes are supported. The four data transmission modes apply to the data after the SOP. In particular the length, data, and CRC16 are all sent in the same mode. In general, lower data rates reduces packet error rate in any given environment.

By combining the DATA\_CODE\_ADR code lengths and data transmission modes described above, the CYRF69213 IC supports the following data rates:

- 1000-kbps (GFSK)
- 250-kbps (32-chip 8DR)
- 125-kbps (64-chip 8DR)
- 62.5-kbps (32-chip DDR)
- 31.25-kbps (64-chip DDR)
- 15.625-kbps (64-chip SDR)

Lower data rates typically provide longer range and/or a more robust link.

#### Link Layer Modes

The CYRF69213 IC device supports the following data packet framing features:

**SOP** – Packets begin with a 2-symbol Start of Packet (SOP) marker. This is required in GFSK and 8DR modes, but is optional in DDR mode and is not supported in SDR mode; if framing is disabled then an SOP event is inferred whenever two successive correlations are detected. The SOP\_CODE\_ADR code used for the SOP is different from that used for the ‘body’ of the packet, and if desired may be a different length. SOP must be configured to be the same length on both sides of the link.

**EOP** – There are two options for detecting the end of a packet. If SOP is enabled, then a packet length field may be enabled. GFSK and 8DR must enable the length field. This is the first 8 bits after the SOP symbol, and is transmitted at the payload data rate. If the length field is enabled, an End of Packet (EOP) condition is inferred after reception of the number of bytes defined in the length field, plus two bytes for the CRC16 (if enabled—see below). The alternative to using the length field is to infer an EOP condition from a configurable number of successive non-correlations; this option is not available in GFSK mode and is only recommended when using SDR mode.

**CRC16** – The device may be configured to append a 16-bit CRC16 to each packet. The CRC16 uses the USB CRC polynomial with the added programmability of the seed. If enabled, the receiver will verify the calculated CRC16 for the payload data against the received value in the CRC16 field. The starting value for the CRC16 calculation is configurable, and the CRC16 transmitted may be calculated using either the loaded seed value or a zero seed; the received data CRC16 will be checked against both the configured and zero CRC16 seeds.

CRC16 detects the following errors:

- Any one bit in error
- Any two bits in error (irrespective of how far apart, which column, and so on)
- Any odd number of bits in error (irrespective of the location)
- An error burst as wide as the checksum itself

Figure 2 on page 7 shows an example packet with SOP, CRC16 and lengths fields enabled.

Figure 2. Example Default Packet Format

**Packet Buffers**

Packet data and configuration registers are accessed through the SPI interface. All configuration registers are directly addressed through the address field in the SPI packet. Configuration registers are provided to allow configuration of DSSS PN codes, data rate, operating mode, interrupt masks, interrupt status, and others.

*Packet Buffers*

All data transmission and reception uses the 16-byte packet buffers—one for transmission and one for reception.

The transmit buffer allows a complete packet of up to 16 bytes of payload data to be loaded in one burst SPI transaction. This is then transmitted with no further MCU intervention. Similarly, the receive buffer allows an entire packet of payload data up to 16 bytes to be received with no firmware intervention required until packet reception is complete.

The CYRF69213 IC supports packet length of up to 40 bytes; interrupts are provided to allow an MCU to use the transmit and receive buffers as FIFOs. When transmitting a packet longer than 16 bytes, the MCU can load 16 bytes initially, and add further bytes to the transmit buffer as transmission of data creates space in the buffer. Similarly, when receiving packets longer than 16 bytes, the MCU function must fetch received data from the FIFO periodically during packet reception to prevent it from overflowing.

**Auto Transaction Sequencer (ATS)**

The CYRF69213 IC provides automated support for transmission and reception of acknowledged data packets.

When transmitting a data packet, the device automatically starts the crystal and synthesizer, enters transmit mode, transmits the packet in the transmit buffer, and then automatically switches to receive mode and waits for a handshake packet—and then automatically reverts to sleep mode or idle mode when either an ACK packet is received, or a timeout period expires.

Similarly, when receiving in transaction mode, the device waits in receive mode for a valid packet to be received, then automatically transitions to transmit mode, transmits an ACK packet, and then switches back to receive mode to await the next packet. The contents of the packet buffers are not affected by the transmission or reception of ACK packets.

In each case, the entire packet transaction takes place without any need for MCU firmware action; to transmit data the MCU simply needs to load the data packet to be transmitted, set the length, and set the TX GO bit. Similarly, when receiving packets in transaction mode, firmware simply needs to retrieve the fully

received packet in response to an interrupt request indicating reception of a packet.

**Interrupts**

The radio function provides an interrupt (IRQ) output, which is configurable to indicate the occurrence of various different events. The IRQ pin may be programmed to be either active high or active low, and be either a CMOS or open drain output. The IRQ pin can be multiplexed on the SPI if routed to an external pin.

The radio function features three sets of interrupts: transmit, receive, and system interrupts. These interrupts all share a single pin (IRQ), but can be independently enabled/disabled. In transmit mode, all receive interrupts are automatically disabled, and in receive mode all transmit interrupts are automatically disabled. However, the contents of the enable registers are preserved when switching between transmit and receive modes.

If more than one radio interrupt is enabled at any time, it is necessary to read the relevant status register to determine which event caused the IRQ pin to assert. Even when a given interrupt source is disabled, the status of the condition that would otherwise cause an interrupt can be determined by reading the appropriate status register. It is therefore possible to use the devices without making use of the IRQ pin by polling the status register(s) to wait for an event, rather than using the IRQ pin.

The microcontroller function supports 23 maskable interrupts in the vectored interrupt controller. Interrupt sources include a USB bus reset, LVR/POR, a programmable interval timer, a 1.024-ms output from the Free Running Timer, three USB endpoints, two capture timers, five GPIO Ports, three GPIO pins, two SPI, a 16-bit free running timer wrap, an internal wake-up timer, and a bus active interrupt. The wake-up timer causes periodic interrupts when enabled. The USB endpoints interrupt after a USB transaction complete is on the bus. The capture timers interrupt whenever a new timer value is saved due to a selected GPIO edge event. A total of eight GPIO interrupts support both TTL or CMOS thresholds. For additional flexibility, on the edge sensitive GPIO pins, the interrupt polarity is programmable to be either rising or falling.

**Clocks**

The radio function has a 12-MHz crystal (30-ppm or better) directly connected between XTAL and GND without the need for external capacitors. A digital clock out function is provided, with selectable output frequencies of 0.75, 1.5, 3, 6, or 12 MHz. This output may be used to clock an external microcontroller (MCU) or ASIC. This output is enabled by default, but may be disabled.

Below are the requirements for the crystal to be directly connected to XTAL pin and GND:

- Nominal Frequency: 12 MHz
- Operating Mode: Fundamental Mode
- Resonance Mode: Parallel Resonant
- Frequency Initial Stability:  $\pm 30$  ppm
- Series Resistance:  $\leq 60$  ohms
- Load Capacitance: 10 pF
- Drive Level: 100  $\mu$ W

The MCU function features an internal oscillator. With the presence of USB traffic, the internal oscillator can be set to precisely tune to USB timing requirements ( $24 \text{ MHz} \pm 1.5\%$ ). The clock generator provides the 12-MHz and 24-MHz clocks that remain internal to the microcontroller.

### GPIO Interface

The MCU function features up to 20 general-purpose IO (GPIO) pins to support USB, PS/2, and other applications. The IO pins are grouped into five ports (Port 0 to 4). The pins on Port 0 and Port 1 may each be configured individually while the pins on Ports 2, 3, and 4 may only be configured as a group. Each GPIO port supports high-impedance inputs, configurable pull up, open drain output, CMOS/TTL inputs, and CMOS output with up to five pins that support programmable drive strength of up to 50-mA sink current. GPIO Port 1 features four pins that interface at a voltage level of 3.3 volts. Additionally, each IO pin can be used to generate a GPIO interrupt to the microcontroller. Each GPIO port has its own GPIO interrupt vector with the exception of GPIO Port 0. GPIO Port 0 has three dedicated pins that have independent interrupt vectors (P0.3–P0.4).

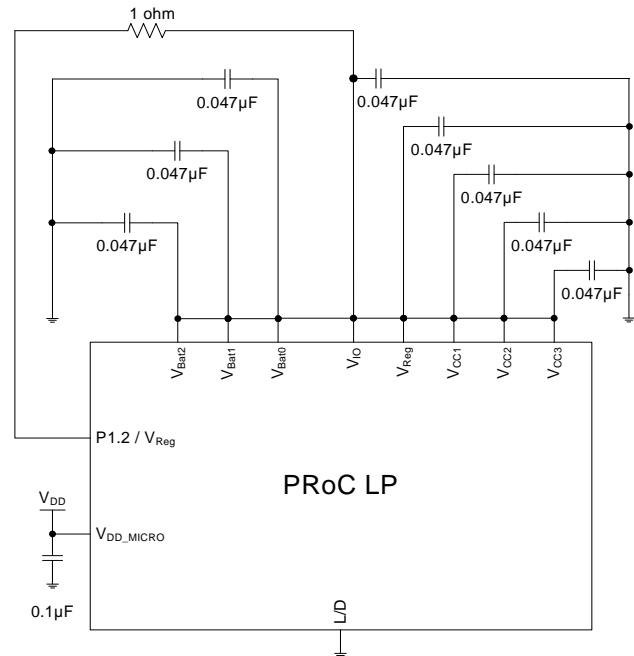

### Power-On Reset/Low-Voltage Detect

The power-on reset circuit detects logic when power is applied to the device, resets the logic to a known state, and begins executing instructions at Flash address 0x0000. When power falls below a programmable trip voltage, it generates reset or may be configured to generate interrupt. There is a low-voltage detect circuit that detects when  $V_{CC}$  drops below a programmable trip voltage. It may be configurable to generate an LVD interrupt to inform the processor about the low-voltage event. POR and LVD share the same interrupt. There is not a separate interrupt for each. The Watchdog timer can be used to ensure the firmware never gets stalled in an infinite loop.

### Power Management

The device draws its power supply from the USB  $V_{bus}$  line. The  $V_{bus}$  supplies power to the MCU function, which has an internal 3.3 V regulator. This 3.3 V is supplied to the radio function via P1.2/ $V_{REG}$  after proper filtering as shown in Figure 3.

Figure 3. Power Management From Internal Regulator

### Timers

The free-running 16-bit timer provides two interrupt sources: the programmable interval timer with 1- $\mu$ s resolution and the 1.024-ms outputs. The timer can be used to measure the duration of an event under firmware control by reading the timer at the start and at the end of an event, then calculating the difference between the two values.

### USB Interface

The MCU function includes an integrated USB serial interface engine (SIE) that allows the chip to easily interface to a USB host. The hardware supports one USB device address with three endpoints.

### Low Noise Amplifier (LNA) and Received Signal Strength Indication (RSSI)

The gain of the receiver may be controlled directly by clearing the AGC EN bit and writing to the Low Noise Amplifier (LNA) bit of the RX\_CFG\_ADR register. When the LNA bit is cleared, the receiver gain is reduced by approximately 20 dB, allowing accurate reception of very strong received signals (for example when operating a receiver very close to the transmitter). An additional 20 dB of receiver attenuation can be added by setting the Attenuation (ATT) bit; this allows data reception to be limited to devices at very short ranges. Disabling AGC and enabling LNA is recommended unless receiving from a device using external PA.

The RSSI register returns the relative signal strength of the on-channel signal power.

When receiving, the device may be configured to automatically measure and store the relative strength of the signal being received as a 5-bit value. When enabled, an RSSI reading is

taken and may be read through the SPI interface. An RSSI reading is taken automatically when the start of a packet is detected. In addition, a new RSSI reading is taken every time the previous reading is read from the RSSI register, allowing the background RF energy level on any given channel to be easily measured when RSSI is read when no signal is being received. A new reading can occur as fast as once every 12  $\mu$ s.

### SPI Interface

The SPI interface between the MCU function and the radio function is a 3-wire SPI Interface. The three pins are MOSI (Master Out Slave In), SCK (Serial Clock), SS (Slave Select). There is an alternate 4-wire MISO Interface that requires the connection of two external pins. The SPI interface is controlled by configuring the SPI Configure Register (SICR Address: 0x3D).

### 3-Wire SPI Interface

The radio function receives a clock from the MCU function on the SCK pin. The MOSI pin is multiplexed with the MISO pin. Bidirectional data transfer takes place between the MCU function and the radio function through this multiplexed MOSI pin. When using this mode the user firmware should ensure that the MOSI pin on the MCU function is in a high impedance state, except when the MCU is actively transmitting data. Firmware must also control the direction of data flow and switch directions between MCU function and radio function by setting the SWAP bit [Bit 7] of the SPI Configure Register. The SS pin is asserted prior to initiating a data transfer between the MCU function and the radio function. The IRQ function may be optionally multiplexed with the MOSI pin; when this option is enabled the IRQ function is not available while the SS pin is low. When using this configuration, user firmware should ensure that the MOSI function on MCU function is in a high-impedance state whenever SS is high.

Figure 4. 3-Wire SPI Mode

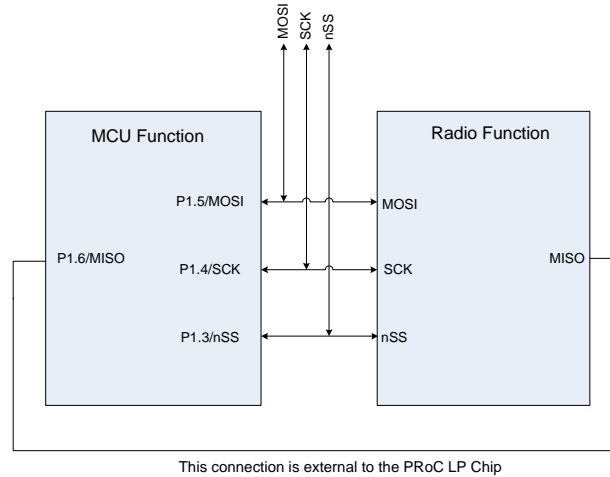

### 4-Wire SPI Interface

The 4-wire SPI communications interface consists of MOSI, MISO, SCK, and SS.

The device receives SCK from the MCU function on the SCK pin. Data from the MCU function is shifted in on the MOSI pin. Data

to the MCU function is shifted out on the MISO pin. The active low SS pin must be asserted for the two functions to communicate. The IRQ function may be optionally multiplexed with the MOSI pin; when this option is enabled the IRQ function is not available while the SS pin is low. When using this configuration, user firmware should ensure that the MOSI function on MCU function is in a high-impedance state whenever SS is high.

Figure 5. 4-WIRE SPI Mode

### SPI Communication and Transactions

The SPI transactions can be single byte or multi-byte. The MCU function initiates a data transfer through a Command/Address byte. The following bytes are data bytes. The SPI transaction format is shown in Figure 6.

The DIR bit specifies the direction of data transfer. 0 = Master reads from slave. 1 = Master writes to slave.

The INC bit helps to read or write consecutive bytes from contiguous memory locations in a single burst mode operation.

If Slave Select is asserted and INC = 1, then the master MCU function reads a byte from the radio, the address is incremented by a byte location, and then the byte at that location is read, and so on. If Slave Select is asserted and INC = 0, then the MCU function reads/writes the bytes in the same register in burst mode, but if it is a register file then it reads/writes the bytes in that register file.

The SPI interface between the radio function and the MCU is not dependent on the internal 12-MHz oscillator of the radio. Therefore, radio function registers can be read from or written into while the radio is in sleep mode.

### SPI IO Voltage References

The SPI interfaces between MCU function and the radio and the IRQ and RST have a separate voltage reference  $V_{IO}$ , enabling the radio function to directly interface with the MCU function, which operates at higher supply voltage. The internal SPIO pins between the MCU function and radio function should be connected with a regulated voltage of 3.3V (by setting [bit4] of Registers P13CR, P14CR, P15CR, and P16CR of the MCU function) and the internal 3.3V regulator of the MCU function should be turned on.

**SPI Connects to External Devices**

The three SPI wires, MOSI, SCK, and SS are also drawn out of the package as external pins to allow the user to interface their own external devices (such as optical sensors and others)

through SPI. The radio function also has its own SPI wires MISO and IRQ, which can be used to send data back to the MCU function or send an interrupt request to the MCU function. They can also be configured as GPIO pins.

**Figure 6. SPI Transaction Format**

|                 | Byte 1 |     |         | Byte 1+N |
|-----------------|--------|-----|---------|----------|
| <b>Bit#</b>     | 7      | 6   | [5:0]   | [7:0]    |
| <b>Bit Name</b> | DIR    | INC | Address | Data     |

**CPU Architecture**

This family of microcontrollers is based on a high-performance, 8-bit, Harvard-architecture microprocessor. Five registers control the primary operation of the CPU core. These registers are affected by various instructions, but are not directly accessible through the register space by the user.

**Table 4. CPU Registers and Register Names**

| Register        | Register Name |
|-----------------|---------------|
| Flags           | CPU_F         |
| Program Counter | CPU_PC        |
| Accumulator     | CPU_A         |
| Stack Pointer   | CPU_SP        |
| Index           | CPU_X         |

The 16-bit Program Counter Register (CPU\_PC) allows for direct addressing of the full eight Kbytes of program memory space.

The Accumulator Register (CPU\_A) is the general-purpose register that holds the results of instructions that specify any of the source addressing modes.

The Index Register (CPU\_X) holds an offset value that is used in the indexed addressing modes. Typically, this is used to address a block of data within the data memory space.

The Stack Pointer Register (CPU\_SP) holds the address of the current top-of-stack in the data memory space. It is affected by the PUSH, POP, LCALL, CALL, RETI, and RET instructions, which manage the software stack. It can also be affected by the SWAP and ADD instructions.

The Flag Register (CPU\_F) has three status bits: Zero Flag bit [1]; Carry Flag bit [2]; Supervisory State bit [3]. The Global Interrupt Enable bit [0] is used to globally enable or disable interrupts. The user cannot manipulate the Supervisory State status bit [3]. The flags are affected by arithmetic, logic, and shift operations. The manner in which each flag is changed is dependent upon the instruction being executed (for example, AND, OR, XOR). See [Table 21](#).

## CPU Registers

### Flags Register

The Flags Register can only be set or reset with logical instruction.

**Table 5. CPU Flags Register (CPU\_F) [R/W]**

| Bit #      | 7        | 6 | 5 | 4   | 3     | 2     | 1    | 0         |
|------------|----------|---|---|-----|-------|-------|------|-----------|
| Field      | Reserved |   |   | XIO | Super | Carry | Zero | Global IE |
| Read/Write | –        | – | – | R/W | R     | RW    | RW   | RW        |
| Default    | 0        | 0 | 0 | 0   | 0     | 0     | 1    | 0         |

**Bits 7:5** Reserved

**Bit 4** XIO  
Set by the user to select between the register banks  
0 = Bank 0  
1 = Bank 1

**Bit 3** Super  
Indicates whether the CPU is executing user code or Supervisor Code. (This code cannot be accessed directly by the user.)  
0 = User Code  
1 = Supervisor Code

**Bit 2** Carry  
Set by CPU to indicate whether there has been a carry in the previous logical/arithmetic operation  
0 = No Carry  
1 = Carry

**Bit 1** Zero  
Set by CPU to indicate whether there has been a zero result in the previous logical/arithmetic operation  
0 = Not Equal to Zero  
1 = Equal to Zero

**Bit 0** Global IE  
Determines whether all interrupts are enabled or disabled  
0 = Disabled  
1 = Enabled

**Note** CPU\_F register is only readable with explicit register address 0xF7. The *OR F, expr* and *AND F, expr* instructions must be used to set and clear the CPU\_F bits

### Accumulator Register

**Table 6. CPU Accumulator Register (CPU\_A)**

| Bit #      | 7                     | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|------------|-----------------------|---|---|---|---|---|---|---|
| Field      | CPU Accumulator [7:0] |   |   |   |   |   |   |   |
| Read/Write | –                     | – | – | – | – | – | – | – |
| Default    | 0                     | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**Bits 7:0** CPU Accumulator [7:0]  
8-bit data value holds the result of any logical/arithmetic instruction that uses a source addressing mode

**Index Register**

**Table 7. CPU X Register (CPU\_X)**

| Bit #      | 7       | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|------------|---------|---|---|---|---|---|---|---|
| Field      | X [7:0] |   |   |   |   |   |   |   |
| Read/Write | –       | – | – | – | – | – | – | – |
| Default    | 0       | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**Bits 7:0** X [7:0]

8-bit data value holds an index for any instruction that uses an indexed addressing mode

**Stack Pointer Register**

**Table 8. CPU Stack Pointer Register (CPU\_SP)**

| Bit #      | 7                   | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|------------|---------------------|---|---|---|---|---|---|---|
| Field      | Stack Pointer [7:0] |   |   |   |   |   |   |   |
| Read/Write | –                   | – | – | – | – | – | – | – |
| Default    | 0                   | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**Bits 7:0** Stack Pointer [7:0]

8-bit data value holds a pointer to the current top-of-stack

**CPU Program Counter High Register**

**Table 9. CPU Program Counter High Register (CPU\_PCH)**

| Bit #      | 7                      | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|------------|------------------------|---|---|---|---|---|---|---|
| Field      | Program Counter [15:8] |   |   |   |   |   |   |   |
| Read/Write | –                      | – | – | – | – | – | – | – |
| Default    | 0                      | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**Bits 7:0** Program Counter [15:8]

8-bit data value holds the higher byte of the program counter

**CPU Program Counter Low Register**

**Table 10. CPU Program Counter Low Register (CPU\_PCL)**

| Bit #      | 7                     | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|------------|-----------------------|---|---|---|---|---|---|---|
| Field      | Program Counter [7:0] |   |   |   |   |   |   |   |
| Read/Write | –                     | – | – | – | – | – | – | – |
| Default    | 0                     | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**Bits 7:0** Program Counter [7:0]

8-bit data value holds the lower byte of the program counter

## Addressing Modes

Examples of the different addressing modes are discussed in this section and example code is given.

### Source Immediate

The result of an instruction using this addressing mode is placed in the A register, the F register, the SP register, or the X register, which is specified as part of the instruction opcode. Operand 1 is an immediate value that serves as a source for the instruction. Arithmetic instructions require two sources. Instructions using this addressing mode are two bytes in length.

**Table 11. Source Immediate**

| Opcode      | Operand 1       |
|-------------|-----------------|
| Instruction | Immediate Value |

#### Examples

```
ADD A, 7 ;In this case, the immediate value
;of 7 is added with the Accumulator,
;and the result is placed in the
;Accumulator.

MOV X, 8 ;In this case, the immediate value
;of 8 is moved to the X register.

AND F, 9 ;In this case, the immediate value
;of 9 is logically ANDed with the F
;register and the result is placed
;in the F register.
```

### Source Direct

The result of an instruction using this addressing mode is placed in either the A register or the X register, which is specified as part of the instruction opcode. Operand 1 is an address that points to a location in either the RAM memory space or the register space that is the source for the instruction. Arithmetic instructions require two sources; the second source is the A register or X register specified in the opcode. Instructions using this addressing mode are two bytes in length.

**Table 12. Source Direct**

| Opcode      | Operand 1      |
|-------------|----------------|
| Instruction | Source Address |

#### Examples

```
ADD A, [7] ;In this case, the value in
;the RAM memory location at
;address 7 is added with the
;Accumulator, and the result
;is placed in the Accumulator.

MOV X, REG[8] ;In this case, the value in
;the register space at address
;8 is moved to the X register.
```

### Source Indexed

The result of an instruction using this addressing mode is placed in either the A register or the X register, which is specified as part of the instruction opcode. Operand 1 is added to the X register forming an address that points to a location in either the RAM memory space or the register space that is the source for the instruction. Arithmetic instructions require two sources; the second source is the A register or X register specified in the opcode. Instructions using this addressing mode are two bytes in length.

**Table 13. Source Indexed**

| Opcode      | Operand 1    |
|-------------|--------------|
| Instruction | Source Index |

#### Examples

```
ADD A, [X+7] ;In this case, the value in
;the memory location at
;address X + 7 is added with
;the Accumulator, and the
;result is placed in the
;Accumulator.

MOV X, REG[X+8] ;In this case, the value in
;the register space at
;address X + 8 is moved to
;the X register.
```

### Destination Direct

The result of an instruction using this addressing mode is placed within either the RAM memory space or the register space. Operand 1 is an address that points to the location of the result. The source for the instruction is either the A register or the X register, which is specified as part of the instruction opcode. Arithmetic instructions require two sources; the second source is the location specified by Operand 1. Instructions using this addressing mode are two bytes in length.

**Table 14. Destination Direct**

| Opcode      | Operand 1           |
|-------------|---------------------|
| Instruction | Destination Address |

#### Examples

```
ADD [7], A ;In this case, the value in
;the memory location at
;address 7 is added with the
;Accumulator, and the result
;is placed in the memory
;location at address 7. The
;Accumulator is unchanged.

MOV REG[8], A ;In this case, the Accumula-
;tor is moved to the regis-
;ter space location at
;address 8. The Accumulator
;is unchanged.
```

### Destination Indexed

The result of an instruction using this addressing mode is placed within either the RAM memory space or the register space. Operand 1 is added to the X register forming the address that points to the location of the result. The source for the instruction is the A register. Arithmetic instructions require two sources; the second source is the location specified by Operand 1 added with the X register. Instructions using this addressing mode are two bytes in length.

**Table 15. Destination Indexed**

| Opcode      | Operand 1         |
|-------------|-------------------|
| Instruction | Destination Index |

#### Example

```
ADD [X+7], A ;In this case, the value in the
              ;memory location at address X+7
              ;is added with the Accumulator,
              ;and the result is placed in
              ;the memory location at address
              ;x+7. The Accumulator is
              ;unchanged.
```

### Destination Direct Source Immediate

The result of an instruction using this addressing mode is placed within either the RAM memory space or the register space. Operand 1 is the address of the result. The source for the instruction is Operand 2, which is an immediate value. Arithmetic instructions require two sources; the second source is the location specified by Operand 1. Instructions using this addressing mode are three bytes in length.

**Table 16. Destination Direct Immediate**

| Opcode      | Operand 1           | Operand 2       |
|-------------|---------------------|-----------------|
| Instruction | Destination Address | Immediate Value |

#### Examples

```
ADD [7], 5 ;In this case, value in the mem-
            ;ory location at address 7 is
            ;added to the immediate value of
            ;5, and the result is placed in
            ;the memory location at address 7.

MOV REG[8], 6 ;In this case, the immediate
              ;value of 6 is moved into the
              ;register space location at
              ;address 8.
```

### Destination Indexed Source Immediate

The result of an instruction using this addressing mode is placed within either the RAM memory space or the register space. Operand 1 is added to the X register to form the address of the result. The source for the instruction is Operand 2, which is an immediate value. Arithmetic instructions require two sources; the second source is the location specified by Operand 1 added with the X register. Instructions using this addressing mode are three bytes in length.

**Table 17. Destination Indexed Immediate**

| Opcode      | Operand 1         | Operand 2       |
|-------------|-------------------|-----------------|
| Instruction | Destination Index | Immediate Value |

#### Examples

```
ADD [X+7], 5 ;In this case, the value in
              ;the memory location at
              ;address X+7 is added with
              ;the immediate value of 5,
              ;and the result is placed
              ;in the memory location at
              ;address X+7.

MOV REG[X+8], 6 ;In this case, the immedi-
                ;ate value of 6 is moved
                ;into the location in the
                ;register space at
                ;address X+8.
```

#### Destination Direct Source Direct

The result of an instruction using this addressing mode is placed within the RAM memory. Operand 1 is the address of the result. Operand 2 is an address that points to a location in the RAM memory that is the source for the instruction. This addressing mode is only valid on the MOV instruction. The instruction using this addressing mode is three bytes in length.

**Table 18. Destination Direct Source Direct**

| Opcode      | Operand 1           | Operand 2      |
|-------------|---------------------|----------------|
| Instruction | Destination Address | Source Address |

#### Example

```
MOV [7], [8] ;In this case, the value in the
              ;memory location at address 8 is
              ;moved to the memory location at
              ;address 7.
```

### Source Indirect Post Increment

The result of an instruction using this addressing mode is placed in the Accumulator. Operand 1 is an address pointing to a location within the memory space, which contains an address (the indirect address) for the source of the instruction. The indirect address is incremented as part of the instruction execution. This addressing mode is only valid on the MVI instruction. The instruction using this addressing mode is two bytes in length. Refer to the *PSoC Designer: Assembly Language User Guide* for further details on MVI instruction.

**Table 19. Source Indirect Post Increment**

| Opcode      | Operand 1              |
|-------------|------------------------|
| Instruction | Source Address Address |

**Example**

```
MVI A, [8] ;In this case, the value in the
            ;memory location at address 8 is
            ;an indirect address. The memory
            ;location pointed to by the indi-
            ;rect address is moved into the
            ;Accumulator. The indirect
            ;address is then incremented.
```

**Destination Indirect Post Increment**

The result of an instruction using this addressing mode is placed within the memory space. Operand 1 is an address pointing to a location within the memory space, which contains an address (the indirect address) for the destination of the instruction. The indirect address is incremented as part of the instruction execution. The source for the instruction is the Accumulator. This addressing mode is only valid on the MVI instruction. The instruction using this addressing mode is two bytes in length.

**Table 20. Destination Indirect Post Increment**

| Opcode      | Operand 1                   |
|-------------|-----------------------------|
| Instruction | Destination Address Address |

**Example**

```
MVI [8], A ;In this case, the value in
            ;the memory location at
            ;address 8 is an indirect
            ;address. The Accumulator is
            ;moved into the memory loca-
            ;tion pointed to by the indi-
            ;rect address. The indirect
            ;address is then incremented.
```

## Instruction Set Summary

The instruction set is summarized in [Table 21](#) numerically and serves as a quick reference. If more information is needed, the Instruction Set Summary tables are described in detail in the

*PSoc Designer Assembly Language User Guide* (available on the [www.cypress.com](http://www.cypress.com) web site).

**Table 21. Instruction Set Summary Sorted Numerically by Opcode Order<sup>[1, 2]</sup>**

| Opcode Hex | Cycles | Bytes | Instruction Format | Flags | Opcode Hex | Cycles | Bytes | Instruction Format    | Flags           | Opcode Hex | Cycles | Bytes | Instruction Format    | Flags |
|------------|--------|-------|--------------------|-------|------------|--------|-------|-----------------------|-----------------|------------|--------|-------|-----------------------|-------|

**Notes**

1. Interrupt routines take 13 cycles before execution resumes at interrupt vector table.
2. The number of cycles required by an instruction is increased by one for instructions that span 256-byte boundaries in the Flash memory space.

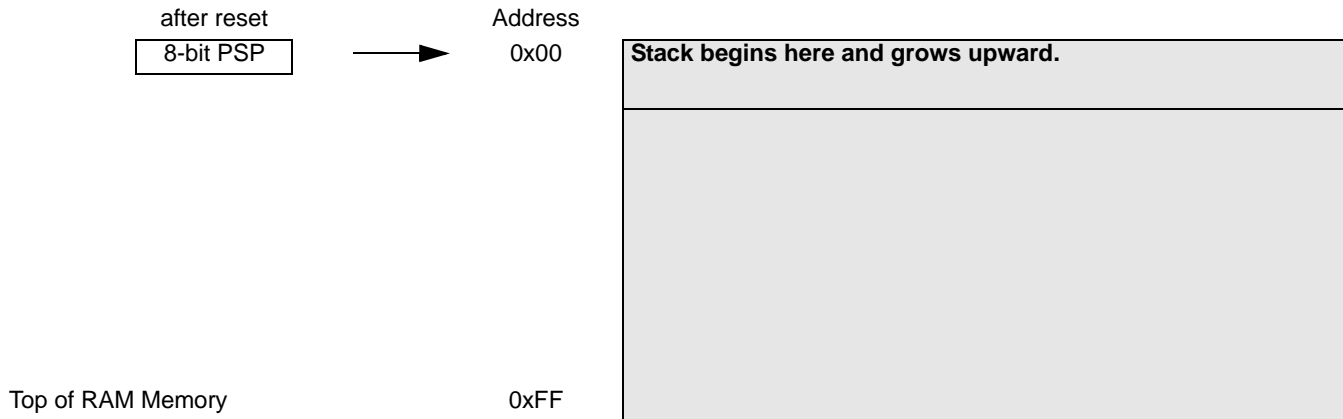

## Data Memory Organization

The MCU function has 256 bytes of data RAM

Figure 7. Data Memory Organization

## Flash

This section describes the Flash block of the CYRF69213. Much of the user-visible Flash functionality, including programming and security, are implemented in the M8C Supervisory Read Only Memory (SROM). CYRF69213 Flash has an endurance of 1000 cycles and 10-year data retention.

### Flash Programming and Security

All Flash programming is performed by code in the SROM. The registers that control the Flash programming are only visible to the M8C CPU when it is executing out of SROM. This makes it impossible to read, write, or erase the Flash by bypassing the security mechanisms implemented in the SROM.

Customer firmware can only program the Flash via SROM calls. The data or code images can be sourced by way of any interface with the appropriate support firmware. This type of programming requires a 'boot-loader'—a piece of firmware resident on the Flash. For safety reasons this boot-loader should not be overwritten during firmware rewrites.

The Flash provides four auxiliary rows that are used to hold Flash block protection flags, boot time calibration values, configuration tables, and any device values. The routines for accessing these auxiliary rows are documented in the SROM section. The auxiliary rows are not affected by the device erase function.

### In-System Programming

Most designs that include an CYRF69213 part will have a USB connector attached to the USB D+/D- pins on the device. These designs require the ability to program or reprogram a part through these two pins alone.

CYRF69213 device enables this type of in-system programming by using the D+ and D- pins as the serial programming mode interface. This allows an external controller to cause the CYRF69213 part to enter serial programming mode and then to use the test queue to issue Flash access functions in the SROM. The programming protocol is not USB.

## SROM

The SROM holds code that is used to boot the part, calibrate circuitry, and perform Flash operations. (Table 23 lists the SROM functions.) The functions of the SROM may be accessed in normal user code or operating from Flash. The SROM exists in a separate memory space from user code. The SROM functions are accessed by executing the Supervisory System Call instruction (SSC), which has an opcode of 00h. Prior to executing the SSC, the M8C's accumulator needs to be loaded with the desired SROM function code from Table 23. Undefined functions will cause a HALT if called from user code. The SROM functions are executing code with calls; therefore, the functions require stack space. With the exception of Reset, all of the SROM functions have a *parameter block* in SRAM that must be configured before executing the SSC. Table 24 lists all possible parameter block variables. The meaning of each parameter, with regards to a specific SROM function, is described later in this section.

Table 23. SROM Function Codes

| Function Code | Function Name | Stack Space |
|---------------|---------------|-------------|
| 00h           | SWBootReset   | 0           |
| 01h           | ReadBlock     | 7           |
| 02h           | WriteBlock    | 10          |
| 03h           | EraseBlock    | 9           |
| 05h           | EraseAll      | 11          |
| 06h           | TableRead     | 3           |
| 07h           | Checksum      | 3           |

Two important variables that are used for all functions are KEY1 and KEY2. These variables are used to help discriminate between valid SSCs and inadvertent SSCs. KEY1 must always have a value of 3Ah, while KEY2 must have the same value as the stack pointer when the SROM function begins execution. This would be the Stack Pointer value when the SSC opcode is executed, plus three. If either of the keys do not match the

expected values, the M8C will halt (with the exception of the SWBootReset function). The following code puts the correct value in KEY1 and KEY2. The code starts with a halt, to force the program to jump directly into the setup code and not run into it.

```
halt
SSCOP: mov [KEY1], 3ah
mov X, SP
mov A, X
add A, 3
mov [KEY2], A
```

**Table 24. SROM Function Parameters**

| Variable Name            | SRAM Address |
|--------------------------|--------------|
| Key1/Counter/Return Code | 0,F8h        |
| Key2/TMP                 | 0,F9h        |
| BlockID                  | 0,FAh        |
| Pointer                  | 0,FBh        |
| Clock                    | 0,FC h       |
| Mode                     | 0,FDh        |
| Delay                    | 0,FEh        |
| PCL                      | 0,FFh        |

The SROM also features Return Codes and Lockouts.

*Return Codes*

Return codes aid in the determination of success or failure of a particular function. The return code is stored in KEY1’s position in the parameter block. The CheckSum and TableRead functions do not have return codes because KEY1’s position in the parameter block is used to return other data.

**Table 25. SROM Return Codes**

| Return Code | Description  |
|-------------|--|
| 00h         | Success  |
| 01h         | Function not allowed due to level of protection on block |
| 02h         | Software reset without hardware reset                    |
| 03h         | Fatal error, SROM halted                                 |

Read, write, and erase operations may fail if the target block is read or write protected. Block protection levels are set during device programming.

The EraseAll function overwrites data in addition to leaving the entire user Flash in the erase state. The EraseAll function loops through the number of Flash macros in the product, executing the following sequence: erase, bulk program all zeros, erase. After all the user space in all the Flash macros are erased, a second loop erases and then programs each protection block with zeros.

**SROM Function Descriptions**

All SROM functions are described in the following sections.

*SWBootReset Function*

The SROM function, SWBootReset, is the function that is responsible for transitioning the device from a reset state to running user code. The SWBootReset function is executed whenever the SROM is entered with an M8C accumulator value of 00h; the SRAM parameter block is not used as an input to the function. This will happen, by design, after a hardware reset, because the M8C’s accumulator is reset to 00h or when user code executes the SSC instruction with an accumulator value of 00h. The SWBootReset function will not execute when the SSC instruction is executed with a bad key value and a nonzero function code. A CYRF69213 device will execute the HALT instruction if a bad value is given for either KEY1 or KEY2.

The SWBootReset function verifies the integrity of the calibration data by way of a 16-bit checksum, before releasing the M8C to run user code.

*ReadBlock Function*

The ReadBlock function is used to read 64 contiguous bytes from Flash—a block.

The first thing this function does is to check the protection bits and determine if the desired BLOCKID is readable. If read protection is turned on, the ReadBlock function will exit, setting the accumulator and KEY2 back to 00h. KEY1 will have a value of 01h, indicating a read failure. If read protection is not enabled, the function will read 64 bytes from the Flash using a ROMX instruction and store the results in SRAM using an MVI instruction. The first of the 64 bytes will be stored in SRAM at the address indicated by the value of the POINTER parameter. When the ReadBlock completes successfully, the accumulator, KEY1, and KEY2 will all have a value of 00h.

**Table 26. ReadBlock Parameters**

| Name    | Address | Description  |
|---------|---------|--|
| KEY1    | 0,F8h   | 3Ah  |
| KEY2    | 0,F9h   | Stack Pointer value, when SSC is executed                          |
| BLOCKID | 0,FAh   | Flash block number   |
| POINTER | 0,FBh   | First of 64 addresses in SRAM where returned data should be stored |

*WriteBlock Function*

The WriteBlock function is used to store data in the Flash. Data is moved 64 bytes at a time from SRAM to Flash using this function. The first thing the WriteBlock function does is to check the protection bits and determine if the desired BLOCKID is writable. If write protection is turned on, the WriteBlock function will exit, setting the accumulator and KEY2 back to 00h. KEY1 will have a value of 01h, indicating a write failure. The configuration of the WriteBlock function is straightforward. The BLOCKID of the Flash block, where the data is stored, must be determined and stored at SRAM address FAh.

The SRAM address of the first of the 64 bytes to be stored in Flash must be indicated using the POINTER variable in the parameter block (SRAM address FBh). Finally, the CLOCK and DELAY values must be set correctly. The CLOCK value determines the length of the write pulse that will be used to store the data in the Flash. The CLOCK and DELAY values are dependent on the CPU speed. Refer to 'Clocking' Section for additional information.

**Table 27. WriteBlock Parameters**

| Name    | Address | Description   |
|---------|---------|---|
| KEY1    | 0,F8h   | 3Ah   |
| KEY2    | 0,F9h   | Stack Pointer value, when SSC is executed   |
| BLOCKID | 0,FAh   | 8-KB Flash block number (00h–7Fh)<br>4-KB Flash block number (00h–3Fh)<br>3-KB Flash block number (00h–2Fh) |
| POINTER | 0,FBh   | First of 64 addresses in SRAM, where the data to be stored in Flash is located prior to calling WriteBlock  |
| CLOCK   | 0,FCh   | Clock divider used to set the write pulse width   |
| DELAY   | 0,FEh   | For a CPU speed of 12 MHz set to 56h  |

*EraseBlock Function*

The EraseBlock function is used to erase a block of 64 contiguous bytes in Flash. The first thing the EraseBlock function does is to check the protection bits and determine if the desired BLOCKID is writable. If write protection is turned on, the EraseBlock function will exit, setting the accumulator and KEY2 back to 00h. KEY1 will have a value of 01h, indicating a write failure. The EraseBlock function is only useful as the first step in programming. Erasing a block will not cause data in a block to be one hundred percent unreadable. If the objective is to obliterate data in a block, the best method is to perform an EraseBlock followed by a WriteBlock of all zeros.

To set up the parameter block for the EraseBlock function, correct key values must be stored in KEY1 and KEY2. The block number to be erased must be stored in the BLOCKID variable and the CLOCK and DELAY values must be set based on the current CPU speed.

**Table 28. EraseBlock Parameters**

| Name    | Address | Description                                     |
|---------|---------|---|
| KEY1    | 0,F8h   | 3Ah   |
| KEY2    | 0,F9h   | Stack Pointer value when SSC is executed        |
| BLOCKID | 0,FAh   | Flash block number (00h–7Fh)                    |
| CLOCK   | 0,FCh   | Clock divider used to set the erase pulse width |
| DELAY   | 0,FEh   | For a CPU speed of 12 MHz set to 56h            |

*ProtectBlock Function*

The CYRF69213 device offers Flash protection on a block-by-block basis. Table 29 lists the protection modes available. In the table, ER and EW are used to indicate the ability to perform external reads and writes. For internal writes, IW is used. Internal reading is always permitted by way of the ROMX instruction. The ability to read by way of the SROM ReadBlock function is indicated by SR. The protection level is stored in two bits according to Table 29. These bits are bit packed into the 64 bytes of the protection block. Therefore, each protection block byte stores the protection level for four Flash blocks. The bits are packed into a byte, with the lowest numbered block's protection level stored in the lowest numbered bits.

The first address of the protection block contains the protection level for blocks 0 through 3; the second address is for blocks 4 through 7. The 64th byte will store the protection level for blocks 252 through 255.

**Table 29. Protection Modes**

| Mode | Settings    | Description            | Marketing       |
|------|-------------|------------------------|-----------------|
| 00b  | SR ER EW IW | Unprotected            | Unprotected     |
| 01b  | SR ER EW IW | Read protect           | Factory upgrade |
| 10b  | SR ER EW IW | Disable external write | Field upgrade   |
| 11b  | SR ER EW IW | Disable internal write | Full protection |

| 7         | 6 | 5         | 4 | 3         | 2 | 1       | 0 |
|-----------|---|-----------|---|-----------|---|---------|---|
| Block n+3 |   | Block n+2 |   | Block n+1 |   | Block n |   |

The level of protection is only decreased by an EraseAll, which places zeros in all locations of the protection block. To set the level of protection, the ProtectBlock function is used. This function takes data from SRAM, starting at address 80h, and ORs it with the current values in the protection block. The result of the OR operation is then stored in the protection block. The EraseBlock function does not change the protection level for a block. Because the SRAM location for the protection data is fixed and there is only one protection block per Flash macro, the ProtectBlock function expects very few variables in the parameter block to be set prior to calling the function. The parameter block values that must be set, besides the keys, are the CLOCK and DELAY values.

**Table 30. ProtectBlock Parameters**

| Name  | Address | Description                                     |
|-------|---------|---|
| KEY1  | 0,F8h   | 3Ah   |
| KEY2  | 0,F9h   | Stack Pointer value when SSC is executed        |
| CLOCK | 0,FCh   | Clock divider used to set the write pulse width |
| DELAY | 0,FEh   | For a CPU speed of 12 MHz set to 56h            |

*EraseAll Function*

The EraseAll function performs a series of steps that destroy the user data in the Flash macros and resets the protection block in each Flash macro to all zeros (the unprotected state). The EraseAll function does not affect the three hidden blocks above the protection block in each Flash macro. The first of these four hidden blocks is used to store the protection table for its eight Kbytes of user data.

The EraseAll function begins by erasing the user space of the Flash macro with the highest address range. A bulk program of all zeros is then performed on the same Flash macro, to destroy all traces of the previous contents. The bulk program is followed by a second erase that leaves the Flash macro in a state ready for writing. The erase, program, erase sequence is then performed on the next lowest Flash macro in the address space if it exists. Following the erase of the user space, the protection block for the Flash macro with the highest address range is erased. Following the erase of the protection block, zeros are written into every bit of the protection table. The next lowest Flash macro in the address space then has its protection block erased and filled with zeros.

The end result of the EraseAll function is that all user data in the Flash is destroyed and the Flash is left in an unprogrammed state, ready to accept one of the various write commands. The protection bits for all user data are also reset to the zero state.

The parameter block values that must be set, besides the keys, are the CLOCK and DELAY values.

**Table 31. EraseAll Parameters**

| Name  | Address | Description                                     |
|-------|---------|---|
| KEY1  | 0,F8h   | 3Ah   |
| KEY2  | 0,F9h   | Stack Pointer value when SSC is executed        |
| CLOCK | 0,FCh   | Clock divider used to set the write pulse width |
| DELAY | 0,FEh   | For a CPU speed of 12 MHz set to 56h            |

*TableRead Function*

The TableRead function gives the user access to part-specific data stored in the Flash during manufacturing. It also returns a Revision ID for the die (not to be confused with the Silicon ID).

**Table 32. Table Read Parameters**

| Name    | Address | Description                              |
|---------|---------|--|
| KEY1    | 0,F8h   | 3Ah                                      |
| KEY2    | 0,F9h   | Stack Pointer value when SSC is executed |
| BLOCKID | 0,FAh   | Table number to read                     |

The table space for the CYRF69213 is simply a 64-byte row broken up into eight tables of eight bytes. The tables are

numbered zero through seven. All user and hidden blocks in the CYRF69213 parts consist of 64 bytes.

An internal table holds the Silicon ID and returns the Revision ID. The Silicon ID is returned in SRAM, while the Revision ID is returned in the CPU\_A and CPU\_X registers. The Silicon ID is a value placed in the table by programming the Flash and is controlled by Cypress Semiconductor Product Engineering. The Revision ID is hard coded into the SROM. The Revision ID is discussed in more detail later in this section.

An internal table holds alternate trim values for the device and returns a one-byte internal revision counter. The internal revision counter starts out with a value of zero and is incremented each time one of the other revision numbers is not incremented. It is reset to zero each time one of the other revision numbers is incremented. The internal revision count is returned in the CPU\_A register. The CPU\_X register will always be set to FFh when trim values are read. The BLOCKID value, in the parameter block, is used to indicate which table should be returned to the user. Only the three least significant bits of the BLOCKID parameter are used by the TableRead function for the CYRF69213. The upper five bits are ignored. When the function is called, it transfers bytes from the table to SRAM addresses F8h–FFh.

The M8C's A and X registers are used by the TableRead function to return the die's Revision ID. The Revision ID is a 16-bit value hard coded into the SROM that uniquely identifies the die's design.

*Checksum Function*

The Checksum function calculates a 16-bit checksum over a user specifiable number of blocks, within a single Flash macro (Bank) starting from block zero. The BLOCKID parameter is used to pass in the number of blocks to calculate the checksum over. A BLOCKID value of 1 will calculate the checksum of only block 0, while a BLOCKID value of 0 will calculate the checksum of all 256 user blocks. The 16-bit checksum is returned in KEY1 and KEY2. The parameter KEY1 holds the lower eight bits of the checksum and the parameter KEY2 holds the upper eight bits of the checksum.

The checksum algorithm executes the following sequence of three instructions over the number of blocks times 64 to be checksummed.

```
romx
    add [KEY1], A
adc [KEY2], 0
```

**Table 33. Checksum Parameters**

| Name    | Address | Description                                     |
|---------|---------|---|
| KEY1    | 0,F8h   | 3Ah   |
| KEY2    | 0,F9h   | Stack Pointer value when SSC is executed        |
| BLOCKID | 0,FAh   | Number of Flash blocks to calculate checksum on |

## SRROM Table Read Description

Table 34. SRROM Table

|         | F8h               | F9h              | F8h | F8h | F8h | F8h | F8h | F8h |
|---------|-------------------|------------------|-----|-----|-----|-----|-----|-----|
| Table 0 | Silicon ID [15-8] | Silicon ID [7-0] |     |     |     |     |     |     |
| Table 1 |                   |                  |     |     |     |     |     |     |
| Table 2 |                   |                  |     |     |     |     |     |     |
| Table 3 |                   |                  |     |     |     |     |     |     |
| Table 4 |                   |                  |     |     |     |     |     |     |
| Table 5 |                   |                  |     |     |     |     |     |     |
| Table 6 |                   |                  |     |     |     |     |     |     |
| Table 7 |                   |                  |     |     |     |     |     |     |

The Silicon IDs for enCoRe II devices are stored in SRROM tables in the part, as shown in [Figure 34](#).

The Silicon ID can be read out from the part using SRROM Table reads. This is demonstrated in the following pseudo code. As mentioned in the section [SRROM](#) on page 18, the SRROM variables occupy address F8h through FFh in the SRAM. Each of the variables and their definition is given in the section [SRROM](#) on page 18.

```

// At the end of the SSC command the silicon ID is stored in F8 (MSB) and F9(LSB) of the SRAM
.terminate:
    jmp .terminate

```

## Clocking

The CYRF69213 internal oscillator outputs two frequencies, the Internal 24-MHz Oscillator and the 32-KHz Low-power Oscillator.

The Internal 24-MHz Oscillator is designed such that it may be trimmed to an output frequency of 24 MHz over temperature and voltage variation. With the presence of USB traffic, the Internal 24-MHz Oscillator can be set to precisely tune to USB timing requirements ( $24 \text{ MHz} \pm 1.5\%$ ). Without USB traffic, the Internal 24-MHz Oscillator accuracy is  $24 \text{ MHz} \pm 5\%$  (between  $0^\circ$ – $70^\circ\text{C}$ ). No external components are required to achieve this level of accuracy.

The internal low-speed oscillator of nominally 32 KHz provides a slow clock source for the CYRF69213 in suspend mode, particularly to generate a periodic wake-up interrupt and also to provide a clock to sequential logic during power-up and power-down events when the main clock is stopped. In addition, this oscillator can also be used as a clocking source for the Interval Timer clock (ITMRCLK) and Capture Timer clock (TCAPCLK). The 32-KHz Low-power Oscillator can operate in low-power mode or can provide a more accurate clock in normal mode. The Internal 32-KHz Low-power Oscillator accuracy ranges (between  $0^\circ$  –  $70^\circ \text{C}$ ) as follows:

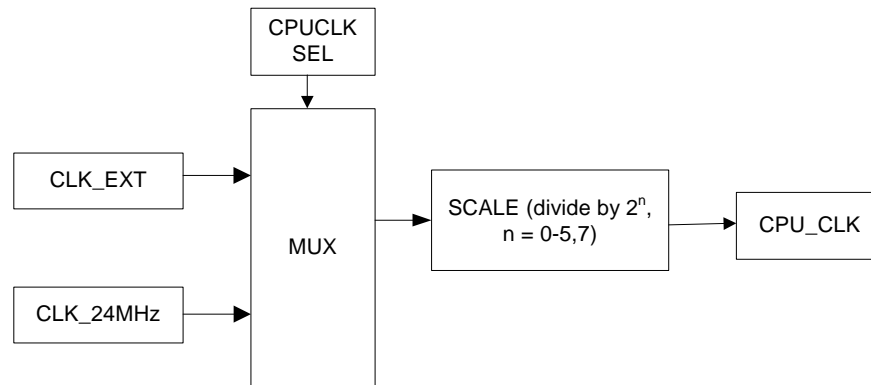

5V Normal mode:  $-8\%$  to  $+16\%$

5V LP mode:  $+12\%$  to  $+48\%$

When using the 32-KHz oscillator the PITMRL/H should be read until two consecutive readings match before sending/receiving data. The following firmware example assumes the developer is interested in the lower byte of the PIT.

```
Read_PIT_counter:
mov A, reg[PITMRL]
mov [57h], A
mov A, reg[PITMRL]
mov [58h], A
mov [59h], A
mov A, reg[PITMRL]

### Clock Architecture Description

The CYRF69213 clock selection circuitry allows the selection of independent clocks for the CPU, USB, Interval Timers, and Capture Timers.

The CPU clock, CPUCLK, can be sourced from the external crystal oscillator or the Internal 24-MHz Oscillator. The selected clock source can optionally be divided by  $2^n$  where  $n$  is 0–5,7 (see Table 38).

USBCLK, which must be 12 MHz for the USB SIE to function properly, can be sourced by the Internal 24-MHz Oscillator or the external crystal oscillator. An optional divide-by-two allows the use of the 24-MHz source.

The Interval Timer clock (ITMRCLK), can be sourced from the external crystal oscillator, the Internal 24-MHz Oscillator, the

Internal 32-KHz Low-power Oscillator, except when in sleep mode, or from the timer capture clock (TCAPCLK). A programmable prescaler of 1, 2, 3, 4 then divides the selected source.

The Timer Capture clock (TCAPCLK) can be sourced from the external crystal oscillator, Internal 24-MHz Oscillator, or the Internal 32-KHz Low-power Oscillator except when in sleep mode.

When it is not being used by the external crystal oscillator, the CLKOUT pin can be driven from one of many sources. This is used for test and can also be used in some applications.

The sources that can drive the CLKOUT are:

- CLKIN after the optional EFTB filter
- Internal 24-MHz Oscillator

- Internal 32-KHz Low-power Oscillator except when in sleep mode
- CPUCLK after the programmable divider

**Table 35. IOSC Trim (IOSCTR) [0x34] [R/W]**

| Bit #      | 7            | 6   | 5   | 4         | 3   | 2   | 1   | 0   |
|------------|--------------|-----|-----|-----------|-----|-----|-----|-----|
| Field      | foffset[2:0] |     |     | Gain[4:0] |     |     |     |     |
| Read/Write | R/W          | R/W | R/W | R/W       | R/W | R/W | R/W | R/W |
| Default    | 0            | 0   | 0   | D         | D   | D   | D   | D   |

The IOSC Calibrate register is used to calibrate the internal oscillator. The reset value is undefined, but during boot the SROM writes a calibration value that is determined during manufacturing test. This value should not require change during normal use. This is the meaning of 'D' in the Default field

**Bits 7:5** foffset [2:0]

This value is used to trim the frequency of the internal oscillator. These bits are not used in factory calibration and will be zero. Setting each of these bits causes the appropriate fine offset in oscillator frequency

- foffset bit 0 = 7.5 KHz
- foffset bit 1 = 15 KHz
- foffset bit 2 = 30 KHz

**Bits 4:0** Gain [4:0]

The effective frequency change of the offset input is controlled through the gain input. A lower value of the gain setting increases the gain of the offset input. This value sets the size of each offset step for the internal oscillator. Nominal gain change (KHz/offsetStep) at each bit, typical conditions (24-MHz operation):

- Gain bit 0 = -1.5 KHz
- Gain bit 1 = -3.0 KHz
- Gain bit 2 = -6 KHz
- Gain bit 3 = -12 KHz
- Gain bit 4 = -24 KHz

**Table 36. LPOSC Trim (LPOSCTR) [0x36] [R/W]**

| Bit #      | 7                | 6        | 5                      | 4   | 3                      | 2   | 1   | 0   |
|------------|------------------|----------|------------------------|-----|------------------------|-----|-----|-----|
| Field      | 32-KHz Low Power | Reserved | 32-KHz Bias Trim [1:0] |     | 32-KHz Freq Trim [3:0] |     |     |     |
| Read/Write | R/W              | —        | R/W                    | R/W | R/W                    | R/W | R/W | R/W |
| Default    | 0                | D        | D                      | D   | D                      | D   | D   | D   |

This register is used to calibrate the 32-KHz Low-speed Oscillator. The reset value is undefined, but during boot the SROM writes a calibration value that is determined during manufacturing test. This value should not require change during normal use. This is the meaning of 'D' in the Default field. If the 32-KHz Low-power bit needs to be written, care should be taken not to disturb the 32-KHz Bias Trim and the 32-KHz Freq Trim fields from their factory calibrated values

**Bit 7** 32-KHz Low Power

- 0 = The 32-KHz Low-speed Oscillator operates in normal mode
- 1 = The 32-KHz Low-speed Oscillator operates in a low-power mode. The oscillator continues to function normally but with reduced accuracy

**Bit 6** Reserved

**Bits 5:4** 32-KHz Bias Trim [1:0]

These bits control the bias current of the low-power oscillator.

- 0 0 = Mid bias
- 0 1 = High bias
- 1 0 = Reserved
- 1 1 = Reserved

**Important Note** Do not program the 32-KHz Bias Trim [1:0] field with the reserved 10b value, as the oscillator does not oscillate at all corner conditions with this setting

**Bits 3:0** 32-KHz Freq Trim [3:0]

These bits are used to trim the frequency of the low-power oscillator

**Table 37. CPU/USB Clock Config CPUCLKCR) [0x30] [R/W]**

| Bit #      | 7        | 6                 | 5              | 4        | 3 | 2 | 1 | 0             |
|------------|----------|-------------------|----------------|----------|---|---|---|---------------|
| Field      | Reserved | USB CLK/2 Disable | USB CLK Select | Reserved |   |   |   | CPUCLK Select |
| Read/Write | –        | R/W               | R/W            | –        | – | – | – | R/W           |
| Default    | 0        | 0                 | 0              | 0        | 0 | 0 | 0 | 0             |

**Bit 7** Reserved

**Bit 6** USB CLK/2 Disable

This bit only affects the USBCLK when the source is the external clock. When the USBCLK source is the Internal 24-MHz Oscillator, the divide by two is always enabled  
 0 = USBCLK source is divided by two. This is the correct setting to use when the Internal 24-MHz Oscillator is used, or when the external source is used with a 24-MHz clock  
 1 = USBCLK is undivided. Use this setting only with a 12-MHz external clock

**Bit 5** USB CLK Select

This bit controls the clock source for the USB SIE  
 0 = Internal 24-MHz Oscillator. With the presence of USB traffic, the Internal 24-MHz Oscillator can be trimmed to meet the USB requirement of 1.5% tolerance (see [Table 39](#))  
 1 = External clock—Internal Oscillator is not trimmed to USB traffic.

**Proper USB SIE operation requires a 12-MHz or 24-MHz clock accurate to <1.5%**

**Bits 4:1** Reserved

**Bit 0** CPU CLK Select

0 = Internal 24-MHz Oscillator  
 1 = External clock—External clock at CLKIN (P0.0) pin

**Note** The CPU speed selection is configured using the OSC\_CR0 Register ([Table 38](#))

**Table 38. OSC Control 0 (OSC\_CR0) [0x1E0] [R/W]**

| Bit #      | 7        | 6 | 5       | 4                 | 3   | 2               | 1   | 0   |
|------------|----------|---|---------|-------------------|-----|-----------------|-----|-----|
| Field      | Reserved |   | No Buzz | Sleep Timer [1:0] |     | CPU Speed [2:0] |     |     |
| Read/Write | –        | – | R/W     | R/W               | R/W | R/W             | R/W | R/W |
| Default    | 0        | 0 | 0       | 0                 | 0   | 0               | 0   | 0   |

**Bits 7:6** Reserved

**Bit 5** No Buzz

During sleep (the Sleep bit is set in the CPU\_SCR Register—Table 42), the LVD and POR detection circuit is turned on periodically to detect any POR and LVD events on the V<sub>CC</sub> pin (the Sleep Duty Cycle bits in the ECO\_TR are used to control the duty cycle—Table 46). To facilitate the detection of POR and LVD events, the No Buzz bit is used to force the LVD and POR detection circuit to be continuously enabled during sleep. This results in a faster response to an LVD or POR event during sleep at the expense of a slightly higher than average sleep current

0 = The LVD and POR detection circuit is turned on periodically as configured in the Sleep Duty Cycle

1 = The Sleep Duty Cycle value is overridden. The LVD and POR detection circuit is always enabled

**Note** The periodic Sleep Duty Cycle enabling is independent with the sleep interval shown in the Sleep [1:0] bits below

**Bits 4:3** Sleep Timer [1:0]

| Sleep Timer [1:0] | Sleep Timer Clock Frequency (Nominal) | Sleep Period (Nominal) | Watchdog Period (Nominal) |
|-------------------|---------------------------------------|------------------------|---------------------------|
| 00                | 512 Hz                                | 1.95 ms                | 6 ms                      |
| 01                | 64 Hz                                 | 15.6 ms                | 47 ms                     |
| 10                | 8 Hz                                  | 125 ms                 | 375 ms                    |
| 11                | 1 Hz                                  | 1 sec                  | 3 sec                     |

**Note** Sleep intervals are approximate

**Bits 2:0** CPU Speed [2:0]

The CYRF69213 may operate over a range of CPU clock speeds. The reset value for the CPU Speed bits is zero; therefore, the default CPU speed is one-eighth of the internal 24 MHz, or 3 MHz

Regardless of the CPU Speed bit's setting, if the actual CPU speed is greater than 12 MHz, the 24-MHz operating requirements apply. An example of this scenario is a device that is configured to use an external clock, which is supplying a frequency of 20 MHz. If the CPU speed register's value is 0b011, the CPU clock will be 20 MHz. Therefore the supply voltage requirements for the device are the same as if the part was operating at 24 MHz. The operating voltage requirements are not relaxed until the CPU speed is at 12 MHz or less

| CPU Speed [2:0] | CPU when Internal Oscillator is selected | External Clock |
|-----------------|--|----------------|
| 000             | 3 MHz (Default)                          | Clock In/8     |
| 001             | 6 MHz                                    | Clock In/4     |
| 010             | 12 MHz                                   | Clock In/2     |
| 011             | 24 MHz                                   | Clock In/1     |
| 100             | 1.5 MHz                                  | Clock In/16    |
| 101             | 750 KHz                                  | Clock In/32    |
| 110             | 187 KHz                                  | Clock In/128   |

**Important Note** Correct USB operations require the CPU clock speed be at least 1.5 MHz or not less than USB clock/8. If the two clocks have the same source then the CPU clock divider should not be set to divide by more than 8. If the two clocks have different sources, care must be taken to ensure that the maximum ratio of USB Clock/CPU Clock can never exceed 8 across the full specification range of both clock sources

**Table 39. USB Osclock Clock Configuration (OSCLCKCR) [0x39] [R/W]**

| Bit #      | 7        | 6 | 5 | 4 | 3 | 2 | 1              | 0                   |
|------------|----------|---|---|---|---|---|----------------|---------------------|
| Field      | Reserved |   |   |   |   |   | Fine Tune Only | USB Osclock Disable |
| Read/Write | –        | – | – | – | – | – | R/W            | R/W                 |
| Default    | 0        | 0 | 0 | 0 | 0 | 0 | 0              | 0                   |

This register is used to trim the Internal 24-MHz Oscillator using received low-speed USB packets as a timing reference. The USB Osclock circuit is active when the Internal 24-MHz Oscillator provides the USB clock

**Bits 7:2** Reserved

**Bit 1** Fine Tune Only  
0 = Enable

1 = Disable the oscillator lock from performing the course-tune portion of its retuning. The oscillator lock must be allowed to perform a course tuning in order to tune the oscillator for correct USB SIE operation. After the oscillator is properly tuned this bit can be set to reduce variance in the internal oscillator frequency that would be caused by course tuning

**Bit 0** USB Osclock Disable

0 = Enable. With the presence of USB traffic, the Internal 24-MHz Oscillator precisely tunes to 24 MHz ± 1.5%  
1 = Disable. The Internal 24-MHz Oscillator is not trimmed based on USB packets. This setting is useful when the internal oscillator is not sourcing the USBSIE clock

**Table 40. Timer Clock Config (TMRCLKCR) [0x31] [R/W]**

| Bit #      | 7              | 6   | 5              | 4   | 3               | 2   | 1              | 0   |
|------------|----------------|-----|----------------|-----|-----------------|-----|----------------|-----|
| Field      | TCAPCL Divider |     | TCAPCLK Select |     | ITMRCLK Divider |     | ITMRCLK Select |     |
| Read/Write | R/W            | R/W | R/W            | R/W | R/W             | R/W | R/W            | R/W |
| Default    | -              | -   | -              | -   | 1               | 1   | 0              | 0   |

**Bits 7:6** TCAPCLK Divider  
TCAPCLK Divider controls the TCAPCLK divisor  
00 = Divide by 2  
01 = Divide by 4  
10 = Divide by 6  
11 = Divide by 8

**Bits 5:4** TCAPCLK Select  
The TCAPCLK Select field controls the source of the TCAPCLK  
0 0 = Internal 24-MHz Oscillator  
0 1 = External crystal oscillator—external crystal oscillator on CLKIN and CLKOUT if the external crystal oscillator is enabled, CLKIN input if the external crystal oscillator is disabled (the XOSC Enable bit of the CLKIOCR Register is cleared—[Table 41](#))  
1 0 = Internal 32-KHz Low-power Oscillator. However this configuration is not used in sleep mode.  
1 1 = TCAPCLK Disabled

**Note** The 1024-μs interval timer is based on the assumption that TCAPCLK is running at 4 MHz. Changes in TCAPCLK frequency will cause a corresponding change in the 1024-μs interval timer frequency

**Bits 3:2** ITMRCLK Divider  
ITMRCLK Divider controls the ITMRCLK divisor.  
0 0 = Divider value of 1  
0 1 = Divider value of 2  
1 0 = Divider value of 3  
1 1 = Divider value of 4

**Bits 1:0** ITMRCLK Select  
0 0 = Internal 24-MHz Oscillator  
0 1 = External crystal oscillator – external crystal oscillator on CLKIN and CLKOUT if the external crystal oscillator is enabled, CLKIN input if the external crystal oscillator is disabled  
1 0 = Internal 32-KHz Low-power Oscillator. However this configuration is not used in sleep mode.  
1 1 = TCAPCLK

*Interval Timer Clock (ITMRCLK)*

The Interval Timer Clock (ITMRCLK) can be sourced from the external crystal oscillator, the Internal 24-MHz oscillator, the internal 32-KHz low-power oscillator except when in sleep mode, or the timer capture clock. A programmable prescaler of 1, 2, 3, or 4 then divides the selected source. The 12-bit Programmable Interval Timer is a simple down counter with a programmable reload value. It provides a 1- $\mu$ s resolution by default. When the down counter reaches zero, the next clock is spent reloading. The reload value can be read and written while the counter is running, but care should be taken to ensure that the counter does not unintentionally reload while the 12-bit reload value is only partially stored—for example, between the two writes of the 12-bit value. The programmable interval timer generates an interrupt to the CPU on each reload.

The parameters to be set will appear on the device editor view of PSoC Designer once you place the CYRF69213 Timer User Module. The parameters are PITIMER\_Source and PITIMER\_Divider. The PITIMER\_Source is the clock to the timer and the PITIMER\_Divider is the value the clock is divided by.

The interval register (PITMR) holds the value that is loaded into the PIT counter on terminal count. The PIT counter is a down counter.

The Programmable Interval Timer resolution is configurable. For example:

TCAPCLK divide by x of CPU clock (for example TCAPCLK divide by 2 of a 24-MHz CPU clock will give a frequency of 12 MHz)

ITMRCLK divide by x of TCAPCLK (for example, ITMRCLK divide by 3 of TCAPCLK is 4 MHz so resolution is 0.25  $\mu$ s)

*Timer Capture Clock (TCAPCLK)*

The Timer Capture clock can be sourced from the external crystal oscillator, internal 24-MHz oscillator or the Internal 332-KHz low-power oscillator except when in sleep mode. A programmable prescaler of 2, 4, 6, or 8 then divides the selected source.

**Figure 9. Programmable Interval Timer Block Diagram**

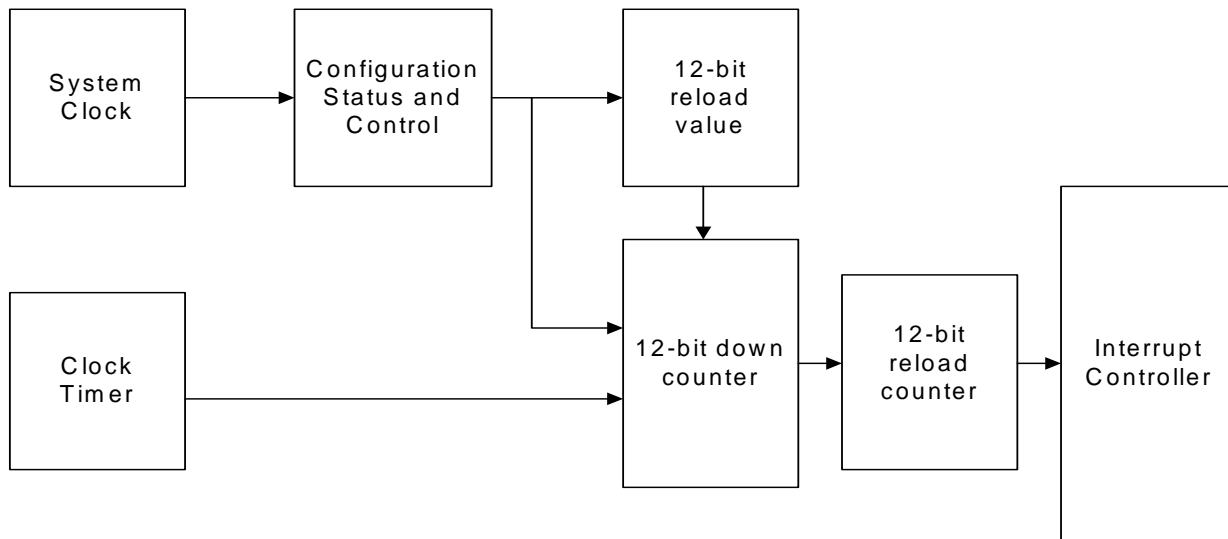

Figure 10. Timer Capture Block Diagram

Table 41. Clock IO Config (CLKIOCR) [0x32] [R/W]

| Bit #      | 7        | 6 | 5 | 4 | 3 | 2 | 1             | 0   |

Bits 7:2 Reserved

Bits 1:0 CLKOUT Select

0 0 = Internal 24-MHz Oscillator

0 1 = External crystal oscillator – external crystal oscillator on CLKIN and CLKOUT if the external crystal oscillator is enabled, CLKIN input if the external oscillator is disabled

1 0 = Internal 32-KHz Low-power Oscillator. However this configuration is not used in sleep mode.

1 1 = CPUCLK

### CPU Clock During Sleep Mode

When the CPU enters sleep mode the CPUCLK Select (Bit [0], Table 37) is forced to the internal oscillator, and the oscillator is stopped. When the CPU comes out of sleep mode it is running on the internal oscillator. The internal oscillator recovery time is three clock cycles of the Internal 32-KHz Low-power Oscillator.

If the system requires the CPU to run off the external clock after awakening from sleep mode, firmware will need to switch the clock source for the CPU.

### Reset

The microcontroller supports two types of resets: Power-on Reset (POR) and Watchdog Reset (WDR). When reset is

initiated, all registers are restored to their default states and all interrupts are disabled.

The occurrence of a reset is recorded in the System Status and Control Register (CPU\_SCR). Bits within this register record the occurrence of POR and WDR Reset respectively. The firmware can interrogate these bits to determine the cause of a reset.

The microcontroller resumes execution from Flash address 0x0000 after a reset. The internal clocking mode is active after a reset, until changed by user firmware.

**Note** The CPU clock defaults to 3 MHz (Internal 24-MHz Oscillator divide-by-8 mode) at POR to guarantee operation at the low V<sub>CC</sub> that might be present during the supply ramp.

**Table 42. System Status and Control Register (CPU\_SCR) [0xFF] [R/W]**

| Bit #      | 7    | 6        | 5                  | 4                  | 3     | 2        | 1 | 0    |
|------------|------|----------|--------------------|--------------------|-------|----------|---|------|
| Field      | GIES | Reserved | WDRS               | PORS               | Sleep | Reserved |   | Stop |
| Read/Write | R    | –        | R/C <sup>[3]</sup> | R/C <sup>[3]</sup> | R/W   | –        | – | R/W  |
| Default    | 0    | 0        | 0                  | 1                  | 0     | 0        | 0 | 0    |

The bits of the CPU\_SCR register are used to convey status and control of events for various functions of an CYRF69213 device

- Bit 7** GIES  
The Global Interrupt Enable Status bit is a read only status bit and its use is discouraged. The GIES bit is a legacy bit, which was used to provide the ability to read the GIE bit of the CPU\_F register. However, the CPU\_F register is now readable. When this bit is set, it indicates that the GIE bit in the CPU\_F register is also set which, in turn, indicates that the microprocessor will service interrupts  
0 = Global interrupts disabled  
1 = Global interrupt enabled
- Bit 6** Reserved
- Bit 5** WDRS  
The WDRS bit is set by the CPU to indicate that a WDR event has occurred. The user can read this bit to determine the type of reset that has occurred. The user can clear but not set this bit  
0 = No WDR  
1 = A WDR event has occurred
- Bit 4** PORS  
The PORS bit is set by the CPU to indicate that a POR event has occurred. The user can read this bit to determine the type of reset that has occurred. The user can clear but not set this bit  
0 = No POR  
1 = A POR event has occurred. (Note that WDR events will not occur until this bit is cleared)
- Bit 3** SLEEP  
Set by the user to enable CPU sleep state. CPU will remain in sleep mode until any interrupt is pending. The Sleep bit is covered in more detail in the [Sleep Mode](#) section  
0 = Normal operation  
1 = Sleep
- Bit 2:1** Reserved
- Bit 0** STOP  
This bit is set by the user to halt the CPU. The CPU will remain halted until a reset (WDR, POR, or external reset) has taken place. If an application wants to stop code execution until a reset, the preferred method would be to use the HALT instruction rather than writing to this bit  
0 = Normal CPU operation  
1 = CPU is halted (not recommended)

**Note**  
3. C = Clear. This bit can only be cleared by the user and cannot be set by firmware

## Power-on Reset

POR occurs every time the power to the device is switched on. POR is released when the supply is typically 2.6V for the upward supply transition, with typically 50 mV of hysteresis during the power-on transient. Bit 4 of the System Status and Control Register (CPU\_SCR) is set to record this event (the register contents are set to 00010000 by the POR). After a POR, the microprocessor is held off for approximately 20 ms for the V<sub>CC</sub> supply to stabilize before executing the first instruction at address 0x00 in the Flash. If the V<sub>CC</sub> voltage drops below the POR downward supply trip point, POR is reasserted. The V<sub>CC</sub> supply needs to ramp linearly from 0 to 4V in 0 to 200 ms.

**Important** The PORS status bit is set at POR and can only be cleared by the user. It cannot be set by firmware.

## Watchdog Timer Reset

The user has the option to enable the WDT. The WDT is enabled by clearing the PORS bit. Once the PORS bit is cleared, the WDT cannot be disabled. The only exception to this is if a POR event takes place, which will disable the WDT.

**Table 43. Reset Watchdog Timer (RESWDT) [0xE3] [W]**

| Bit #      | 7                          | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|------------|----------------------------|---|---|---|---|---|---|---|
| Field      | Reset Watchdog Timer [7:0] |   |   |   |   |   |   |   |
| Read/Write | W                          | W | W | W | W | W | W | W |
| Default    | 0                          | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

Any write to this register will clear Watchdog Timer, a write of 0x38 will also clear the Sleep Timer

**Bits 7:0** Reset Watchdog Timer [7:0]

## Sleep Mode

The CPU can only be put to sleep by the firmware. This is accomplished by setting the Sleep bit in the System Status and Control Register (CPU\_SCR). This stops the CPU from executing instructions, and the CPU will remain asleep until an interrupt comes pending, or there is a reset event (either a Power-on Reset, or a Watchdog Timer Reset).

The Low-voltage Detection circuit (LVD) drops into fully functional power-reduced states, and the latency for the LVD is increased. The actual latency can be traded against power consumption by changing the Sleep Duty Cycle field of the ECO\_TR Register.

The Internal 32-KHz Low-speed Oscillator remains running. Prior to entering suspend mode, firmware can optionally configure the 32-KHz Low-speed Oscillator to operate in a low-power mode to help reduce the overall power consumption (using Bit 7, Table 36). This will help save approximately 5 μA; however, the trade off is that the 32-KHz Low-speed Oscillator will be less accurate.

All interrupts remain active. Only the occurrence of an interrupt will wake the part from sleep. The Stop bit in the System Status and Control Register (CPU\_SCR) must be cleared for a part to resume out of sleep. The Global Interrupt Enable bit of the CPU Flags Register (CPU\_F) does not have any effect. Any unmasked interrupt will wake the system up. As a result, any interrupts not intended for waking must be disabled through the Interrupt Mask Registers.

The sleep timer is used to generate the sleep time period and the Watchdog time period. The sleep timer is clocked by the Internal 32-KHz Low-power Oscillator system clock. The user can program the sleep time period using the Sleep Timer bits of the OSC\_CR0 Register (Table 38). When the sleep time elapses (sleep timer overflows), an interrupt to the Sleep Timer Interrupt Vector will be generated.

The Watchdog Timer period is automatically set to be three counts of the Sleep Timer overflows. This represents between two and three sleep intervals depending on the count in the Sleep Timer at the previous WDT clear. When this timer reaches three, a WDR is generated.

The user can either clear the WDT, or the WDT and the Sleep Timer. Whenever the user writes to the Reset WDT Register (RES\_WDT), the WDT will be cleared. If the data that is written is the hex value 0x38, the Sleep Timer will also be cleared at the same time.

When the CPU enters sleep mode the CPUCLK Select (Bit 1, Table 37) is forced to the Internal Oscillator. The internal oscillator recovery time is three clock cycles of the Internal 32-KHz Low-power Oscillator. The Internal 24-MHz Oscillator restarts immediately on exiting Sleep mode. If an external clock is used, firmware will need to switch the clock source for the CPU.

On exiting sleep mode, once the clock is stable and the delay time has expired, the instruction immediately following the sleep instruction is executed before the interrupt service routine (if enabled).

The Sleep interrupt allows the microcontroller to wake up periodically and poll system components while maintaining very low average power consumption. The Sleep interrupt may also be used to provide periodic interrupts during non-sleep modes.

## Sleep Sequence

The SLEEP bit is an input into the sleep logic circuit. This circuit is designed to sequence the device into and out of the hardware sleep state. The hardware sequence to put the device to sleep is shown in Figure 11 and is defined as follows.

1. Firmware sets the SLEEP bit in the CPU\_SCR0 register. The Bus Request (BRQ) signal to the CPU is immediately asserted. This is a request by the system to halt CPU operation at an instruction boundary. The CPU samples BRQ on the positive edge of CPUCLK.

2. Due to the specific timing of the register write, the CPU issues a Bus Request Acknowledge (BRA) on the following positive edge of the CPU clock. The sleep logic waits for the following negative edge of the CPU clock and then asserts a system-wide Power Down (PD) signal. In Figure 11 the CPU is halted and the system-wide power down signal is asserted.
3. The system-wide PD (power down) signal controls several major circuit blocks: The Flash memory module, the internal 24-MHz oscillator, the EFTB filter and the bandgap voltage reference. These circuits transition into a zero power state. The only operational circuits on chip are the Low Power oscil-

lator, the bandgap refresh circuit, and the supply voltage monitor (POR/LVD) circuit.

**Note** To achieve the lowest possible power consumption during suspend/sleep, the following conditions must be observed in addition to considerations for the sleep timer.

- All GPIOs must be set to outputs and driven low
- The USB pins P1.0 and P1.1 should be configured as inputs with their pull ups enabled.

Figure 11. Sleep Timing

**Wakeup Sequence**

Once asleep, the only event that can wake the system up is an interrupt. The global interrupt enable of the CPU flag register does not need to be set. Any unmasked interrupt will wake the system up. It is optional for the CPU to actually take the interrupt after the wakeup sequence. The wakeup sequence is synchronized to the 32-KHz clock for purposes of sequencing a startup delay, to allow the Flash memory module enough time to power up before the CPU asserts the first read access. Another reason for the delay is to allow the oscillator, Bandgap, and LVD/POR circuits time to settle before actually being used in the system. As shown in Figure 12, the wakeup sequence is as follows:

1. The wakeup interrupt occurs and is synchronized by the negative edge of the 32-KHz clock.
2. At the following positive edge of the 32-KHz clock, the system-wide PD signal is negated. The Flash memory module, internal oscillator, EFTB, and bandgap circuit are all powered up to a normal operating state.
3. At the following positive edge of the 32-KHz clock, the current values for the precision POR and LVD have settled and are sampled.
4. At the following negative edge of the 32-KHz clock (after about 15 μs nominal), the BRQ signal is negated by the sleep logic circuit. On the following CPUCLK, BRA is negated by the CPU and instruction execution resumes. Note that in Figure 12 fixed function blocks, such as Flash, internal oscillator, EFTB, and bandgap, have about 15 μs start up. The wakeup times (interrupt to CPU operational) will range from 75 μs to 105 μs.

**Low Power in Sleep Mode**

The following steps are mandatory before configuring the system into suspend mode to meet the specifications:

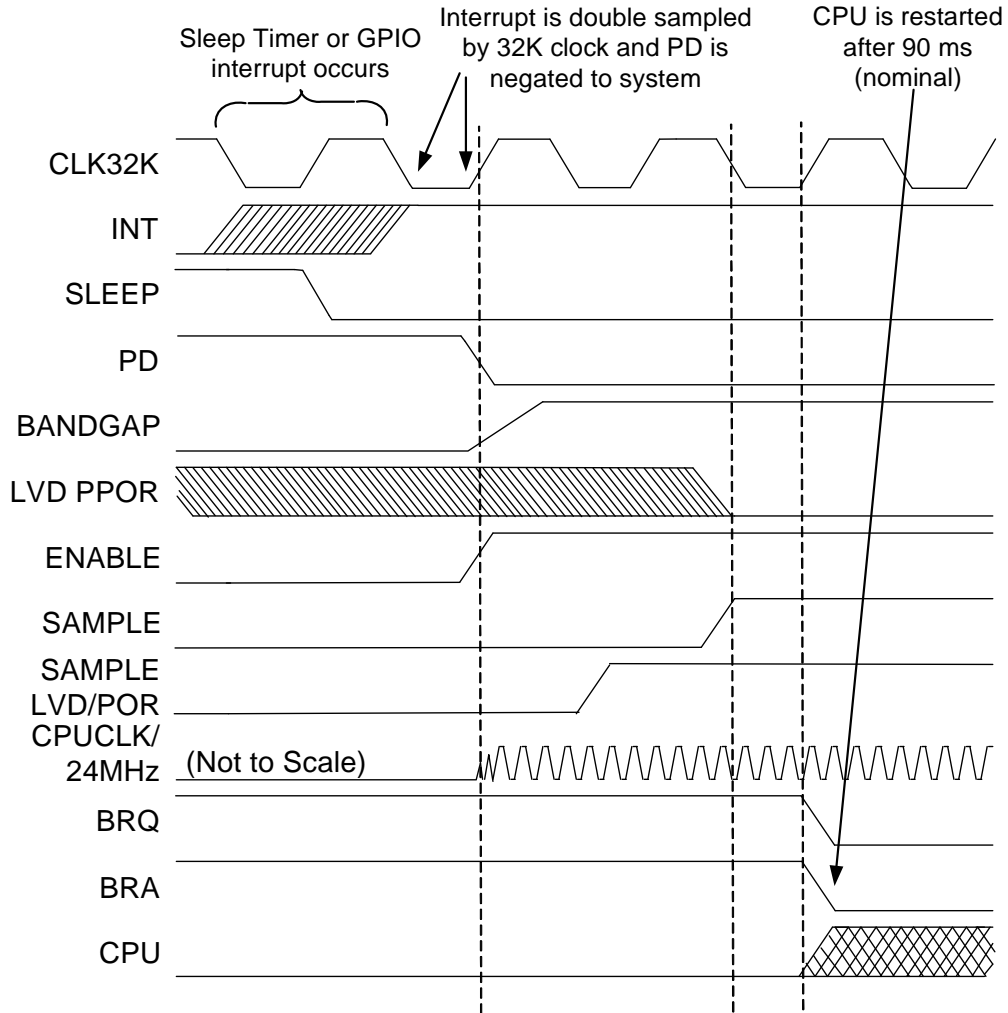

1. Clear P11CR[0], P10CR[0] - during USB and Non-USB operations
2. Clear the USB Enable USBCR[7] - during USB mode operations
3. Set P10CR[1] - during non-USB mode operations
4. To avoid current consumption make sure ITMRCLK, TCPCLK, and USBCLK are not sourced by either low power 32KHz oscillator or 24 MHz crystal-less oscillator.

All the other blocks go to the power down mode automatically on suspend.

The following steps are user configurable and help in reducing the average suspend mode power consumption.

1. Configure the power supply monitor at a large regular intervals, control register bits are 1,EB[7:6] (Power system sleep duty cycle PSSDC[1:0]).
2. Configure the Low power oscillator into low power mode, control register bit is LOPSTR[7].

**Figure 12. Wakeup Timing**

## Low-Voltage Detect Control

**Table 44. Low-voltage Control Register (LVDCR) [0x1E3] [R/W]**

| Bit #      | 7        | 6 | 5           | 4   | 3        | 2       | 1   | 0   |
|------------|----------|---|-------------|-----|----------|---------|-----|-----|
| Field      | Reserved |   | PORLEV[1:0] |     | Reserved | VM[2:0] |     |     |
| Read/Write | –        | – | R/W         | R/W | –        | R/W     | R/W | R/W |
| Default    | 0        | 0 | 0           | 0   | 0        | 0       | 0   | 0   |

This register controls the configuration of the Power-on Reset/Low-voltage Detection block

**Bits 7:6** Reserved

**Bits 5:4** PORLEV[1:0]

This field controls the level below which the precision power-on-reset (PPOR) detector generates a reset

0 0 = 2.7V Range (trip near 2.6V)

0 1 = 3V Range (trip near 2.9V)

1 0 = 5V Range,  $\geq 4.75V$  (trip near 4.65V). This setting must be used when operating the CPU above 12 MHz.

1 1 = PPOR will not generate a reset, but values read from the Voltage Monitor Comparators Register (Table 45) give the internal PPOR comparator state with trip point set to the 3V range setting

**Bit 3** Reserved

**Bits 2:0** VM[2:0]

This field controls the level below which the low-voltage-detect trips—possibly generating an interrupt and the level at which the Flash is enabled for operation.

| VM[2:0] | LVD Trip Point (V) |          |          |
|---------|--------------------|----------|----------|
|         | Min.               | Typical  | Max.     |
| 000     | Reserved           | Reserved | Reserved |
| 001     | Reserved           | Reserved | Reserved |
| 010     | Reserved           | Reserved | Reserved |
| 011     | Reserved           | Reserved | Reserved |
| 100     | 4.439              | 4.48     | 4.528    |
| 101     | 4.597              | 4.64     | 4.689    |
| 110     | 4.680              | 4.73     | 4.774    |

## POR Compare State

**Table 45. Voltage Monitor Comparators Register (VLTCMP) [0x1E4] [R]**

| Bit #      | 7        | 6 | 5 | 4 | 3 | 2 | 1   | 0    |
|------------|----------|---|---|---|---|---|-----|------|
| Field      | Reserved |   |   |   |   |   | LVD | PPOR |
| Read/Write | –        | – | – | – | – | – | R   | R    |
| Default    | 0        | 0 | 0 | 0 | 0 | 0 | 0   | 0    |

This read-only register allows reading the current state of the Low-voltage-Detection and Precision-Power-On-Reset comparators

**Bits 7:2** Reserved

**Bit 1** LVD

This bit is set to indicate that the low-voltage-detect comparator has tripped, indicating that the supply voltage has gone below the trip point set by VM[2:0] (See Table 44)

0 = No low-voltage-detect event

1 = A low-voltage-detect has tripped

**Bit 0** PPOR

This bit is set to indicate that the precision-power-on-reset comparator has tripped, indicating that the supply voltage is below the trip point set by PORLEV[1:0]

0 = No precision-power-on-reset event

1 = A precision-power-on-reset event has tripped

### ECO Trim Register

**Table 46. ECO (ECO\_TR) [0x1EB] [R/W]**

| Bit #      | 7                      | 6   | 5        | 4 | 3 | 2 | 1 | 0 |
|------------|------------------------|-----|----------|---|---|---|---|---|
| Field      | Sleep Duty Cycle [1:0] |     | Reserved |   |   |   |   |   |
| Read/Write | R/W                    | R/W | –        | – | – | – | – | – |
| Default    | 0                      | 0   | 0        | 0 | 0 | 0 | 0 | 0 |

This register controls the ratios (in numbers of 32-KHz clock periods) of ‘on’ time versus ‘off’ time for LVD and POR detection circuit

- Bits 7:6** Sleep Duty Cycle [1:0]  
 0 0 = 1/128 periods of the Internal 32-KHz Low-speed Oscillator  
 0 1 = 1/512 periods of the Internal 32-KHz Low-speed Oscillator  
 1 0 = 1/32 periods of the Internal 32-KHz Low-speed Oscillator  
 1 1 = 1/8 periods of the Internal 32-KHz Low-speed Oscillator

### General-Purpose IO Ports

The general-purpose IO ports are discussed in the following sections.

#### Port Data Registers

**Table 47. P0 Data Register (P0DATA)[0x00] [R/W]**

| Bit #      | 7    | 6        | 5        | 4         | 3         | 2        | 1    | 0        |
|------------|------|----------|----------|-----------|-----------|----------|------|----------|
| Field      | P0.7 | Reserved | Reserved | P0.4/INT2 | P0.3/INT1 | Reserved | P0.1 | Reserved |
| Read/Write | R/W  | R/W      | R/W      | R/W       | R/W       | R/W      | R/W  | R/W      |
| Default    | 0    | 0        | 0        | 0         | 0         | 0        | 0    | 0        |

This register contains the data for Port 0. Writing to this register sets the bit values to be output on output enabled pins. Reading from this register returns the current state of the Port 0 pins

- Bit 7** P0.7 Data
- Bits 6:5** Reserved  
 The use of the pins as the P0.6–P0.5 GPIOs and the alternative functions exist in the CYRF69213
- Bits 4:3** P0.4–P0.3 Data/INT2 – INT1  
 In addition to their use as the P0.4–P0.3 GPIOs, these pins can also be used for the alternative functions as the Interrupt pins (INT0–INT2). To configure the P0.4–P0.3 pins, refer to the P0.3/INT1–P0.4/INT2 Configuration Register (Table 51)  
 The use of the pins as the P0.4–P0.3 GPIOs and the alternative functions exist in the CYRF69213
- Bit 2** Reserved
- Bit 1** P0.1
- Bit 0** Reserved

**Table 48. P1 Data Register (P1DATA) [0x01] [R/W]**

| Bit #      | 7    | 6          | 5          | 4         | 3         | 2         | 1       | 0       |
|------------|------|------------|------------|-----------|-----------|-----------|---------|---------|
| Field      | P1.7 | P1.6/SMISO | P1.5/SMOSI | P1.4/SCLK | P1.3/SSEL | P1.2/VREG | P1.1/D- | P1.0/D+ |
| Read/Write | R/W  | R/W        | R/W        | R/W       | R/W       | R/W       | R/W     | R/W     |
| Default    | 0    | 0          | 0          | 0         | 0         | 0         | 0       | 0       |

This register contains the data for Port 1. Writing to this register sets the bit values to be output on output enabled pins. Reading from this register returns the current state of the Port 1 pins

**Bit 7** P1.7 Data

**Bits 6:3** P1.6–P1.3 Data/SPI Pins (SMISO, SMOSI, SCLK, SSEL)

In addition to their use as the P1.6–P1.3 GPIOs, these pins can also be used for the alternative function as the SPI interface pins. To configure the P1.6–P1.3 pins, refer to the P1.3–P1.6 Configuration Register (Table 56)  
The use of the pins as the P1.6–P1.3 GPIOs and the alternative functions exist in all the CYRF69213 parts

**Bit 2** P1.2/VREG

This pin is used as the regulator output. The 3.3V VREG output must be enabled by setting Bit 0 of VREGCR register (Table 80). A 1-mF min, 2-mF max capacitor is required on VREG output.

**Bits 1:0** P1.1–P1.0/D- and D+

When USB mode is disabled (Bit 7 in Table 81 is clear), the P1.1 and P1.0 bits are used to control the state of the P1.0 and P1.1 pins. When the USB mode is enabled, the P1.1 and P1.0 pins are used as the D- and D+ pins, respectively. If the USB Force State bit (Bit 0 in Table 79) is set, the state of the D- and D+ pins can be controlled by writing to the D- and D+ bits

**Table 49. P2 Data Register (P2DATA) [0x02] [R/W]**

| Bit #      | 7        | 6 | 5 | 4 | 3 | 2 | 1         | 0   |
|------------|----------|---|---|---|---|---|-----------|-----|
| Field      | Reserved |   |   |   |   |   | P2.1–P2.0 |     |
| Read/Write | -        | - | - | - | - | - | R/W       | R/W |
| Default    | 0        | 0 | 0 | 0 | 0 | 0 | 0         | 0   |

This register contains the data for Port 2. Writing to this register sets the bit values to be output on output enabled pins. Reading from this register returns the current state of the Port 2 pins

**Bits 7:2** Reserved Data [7:2]

**Bits 1:0** P2 Data [1:0]

## GPIO Port Configuration

All the GPIO configuration registers have common configuration controls. The following are the bit definitions of the GPIO configuration registers.

### Int Enable

When set, the Int Enable bit allows the GPIO to generate interrupts. Interrupt generate can occur regardless of whether the pin is configured for input or output. All interrupts are edge sensitive, however for any interrupt that is shared by multiple sources (that is, Ports 2, 3, and 4) all inputs must be deasserted before a new interrupt can occur.

When clear, the corresponding interrupt is disabled on the pin.

It is possible to configure GPIOs as outputs, enable the interrupt on the pin and then to generate the interrupt by driving the appropriate pin state. This is useful in test and may have value in applications as well.

### Int Act Low

When set, the corresponding interrupt is active on the falling edge.

When clear, the corresponding interrupt is active on the rising edge.

### TTL Thresh

When set, the input has TTL threshold. When clear, the input has standard CMOS threshold.

### High Sink

When set, the output can sink up to 50 mA.

When clear, the output can sink up to 8 mA.

On the CYRF69213, only the P1.7–P1.3 have 50-mA sink drive capability. Other pins have 8-mA sink drive capability.

### Open Drain

When set, the output on the pin is determined by the Port Data Register. If the corresponding bit in the Port Data Register is set, the pin is in high-impedance state. If the corresponding bit in the Port Data Register is clear, the pin is driven low.

When clear, the output is driven LOW or HIGH.

**Pull-up Enable**

When set the pin has a 7K pull up to  $V_{CC}$  (or VREG for ports with V3.3 enabled).

When clear, the pull up is disabled.

**Output Enable**

When set, the output driver of the pin is enabled.

When clear, the output driver of the pin is disabled.

For pins with shared functions there are some special cases.

**VREG Output/SPI Use**

The P1.2 (VREG), P1.3 (SSEL), P1.4 (SCLK), P1.5 (SMOSI) and P1.6 (SMISO) pins can be used for their dedicated functions or for GPIO.

To enable the pin for GPIO, clear the corresponding VREG Output or SPI Use bit. The SPI function controls the output enable for its dedicated function pins when their GPIO enable bit is clear.

**3.3V Drive**

The P1.3 (SSEL), P1.4 (SCLK), P1.5 (SMOSI) and P1.6 (SMISO) pins have an alternate voltage source from the voltage regulator. If the 3.3V Drive bit is set a high level is driven from the voltage regulator instead of from  $V_{CC}$ .

Setting the 3.3V Drive bit does not enable the voltage regulator. That must be done explicitly by setting the VREG Enable bit in the VREGCR Register (Table 80).

**Figure 13. Block Diagram of a GPIO**

**Table 50. P0.1 Configuration (P01CR) [0x06] R/W**

| Bit #      | 7        | 6          | 5           | 4          | 3         | 2          | 1              | 0             |
|------------|----------|------------|-------------|------------|-----------|------------|----------------|---------------|
| Field      | Reserved | Int Enable | Int Act Low | TTL Thresh | High Sink | Open Drain | Pull-up Enable | Output Enable |
| Read/Write | R/W      | R/W        | R/W         | R/W        | R/W       | R/W        | R/W            | R/W           |
| Default    | 0        | 0          | 0           | 0          | 0         | 0          | 0              | 0             |

This register is used to configure P0.1 In the CYRF69213, only 8 mA sink drive capability is available on this pin regardless of the setting of the High Sink bit

**Bit 7:** Reserved

**Table 51. P0.3/INT1–P0.4/INT2 Configuration (P03CR–P04CR) [0x08–0x09] [R/W]**

| Bit #      | 7        | 6 | 5           | 4          | 3        | 2          | 1              | 0             |
|------------|----------|---|-------------|------------|----------|------------|----------------|---------------|
| Field      | Reserved |   | Int Act Low | TTL Thresh | Reserved | Open Drain | Pull-up Enable | Output Enable |
| Read/Write | –        | – | R/W         | R/W        | –        | R/W        | R/W            | R/W           |
| Default    | 0        | 0 | 0           | 0          | 0        | 0          | 0              | 0             |

These registers control the operation of pins P0.3–P0.4, respectively. These pins are shared between the P0.3–P0.4 GPIOs and the INT0–INT2. These registers exist in all CYRF69213 parts. The INT0–INT2 interrupts are different than all the other GPIO interrupts. These pins are connected directly to the interrupt controller to provide three edge-sensitive interrupts with independent interrupt vectors. These interrupts occur on a rising edge when Int act Low is clear and on a falling edge when Int act Low is set. These pins are enabled as interrupt sources in the interrupt controller registers ([Table 77](#) and [Table 75](#))

To use these pins as interrupt inputs configure them as inputs by clearing the corresponding Output Enable. If the INT0–INT2 pins are configured as outputs with interrupts enabled, firmware can generate an interrupt by writing the appropriate value to the P0.3 and P0.4 data bits in the P0 Data Register

Regardless of whether the pins are used as Interrupt or GPIO pins the Int Enable, Int act Low, TTL Threshold, Open Drain, and Pull-up Enable bits control the behavior of the pin

The P0.3/INT1–P0.4/INT2 pins are individually configured with the P03CR (0x08), and P04CR (0x09), respectively.

**Note** Changing the state of the Int Act Low bit can cause an unintentional interrupt to be generated. When configuring these interrupt sources, it is best to follow the following procedure:

1. Disable interrupt source
2. Configure interrupt source
3. Clear any pending interrupts from the source
4. Enable interrupt source

**Table 52. P0.7 Configuration (P07CR) [0x0C] [R/W]**

| Bit #      | 7        | 6          | 5           | 4          | 3        | 2          | 1              | 0             |
|------------|----------|------------|-------------|------------|----------|------------|----------------|---------------|
| Field      | Reserved | Int Enable | Int Act Low | TTL Thresh | Reserved | Open Drain | Pull-up Enable | Output Enable |
| Read/Write | –        | R/W        | R/W         | R/W        | –        | R/W        | R/W            | R/W           |
| Default    | 0        | 0          | 0           | 0          | 0        | 0          | 0              | 0             |

This register controls the operation of pin P0.7.

**Table 53. P1.0/D+ Configuration (P10CR) [0x0D] [R/W]**

| Bit #      | 7        | 6          | 5           | 4        | 3 | 2 | 1        | 0             |
|------------|----------|------------|-------------|----------|---|---|----------|---------------|
| Field      | Reserved | Int Enable | Int Act Low | Reserved |   |   | Reserved | Output Enable |
| Read/Write | R/W      | R/W        | R/W         | –        | – | – | –        | R/W           |
| Default    | 0        | 0          | 0           | 0        | 0 | 0 | 0        | 0             |

This register controls the operation of the P1.0 (D+) pin when the USB interface is not enabled, allowing the pin to be used as a PS2 interface or a GPIO. See [Table 81](#) for information on enabling USB. When USB is enabled, none of the controls in this register have any effect on the P1.0 pin

**Note** The P1.0 is an open drain only output. It can actively drive a signal low, but cannot actively drive a signal high

**Bit 1** PS/2 Pull-up Enable  
 0 = Disable the 5K-ohm pull-up resistors  
 1 = Enable 5K-ohm pull-up resistors for both P1.0 and P1.1. Enable the use of the P1.0 (D+) and P1.1 (D–) pins as a PS2 style interface

**Bit 0** This bit enables the output on P1.0/D+. This bit should be cleared in sleep mode.

**Table 54. P1.1/D– Configuration (P11CR) [0x0E] [R/W]**

| Bit #      | 7        | 6          | 5           | 4        | 3 | 2          | 1        | 0             |
|------------|----------|------------|-------------|----------|---|------------|----------|---------------|
| Field      | Reserved | Int Enable | Int Act Low | Reserved |   | Open Drain | Reserved | Output Enable |
| Read/Write | –        | R/W        | R/W         | –        | – | R/W        | –        | R/W           |
| Default    | 0        | 0          | 0           | 0        | 0 | 0          | 0        | 0             |

This register controls the operation of the P1.1 (D–) pin when the USB interface is not enabled, allowing the pin to be used as a PS2 interface or a GPIO. See [Table 81](#) for information on enabling USB. When USB is enabled, none of the controls in this register have any effect on the P1.1 pin. When USB is disabled, the 5-Kohm pull-up resistor on this pin can be enabled by the PS/2 Pull-up Enable bit of the P10CR Register ([Table 53](#))

**Bit 0** This bit enables the output on P1.1/D-. This bit should be cleared in sleep mode.

**Note** There is no 2-mA sourcing capability on this pin. The pin can only sink 5 mA at  $V_{OL3}$

**Table 55. P1.2 Configuration (P12CR) [0x0F] [R/W]**

| Bit #      | 7          | 6          | 5           | 4             | 3        | 2          | 1              | 0             |
|------------|------------|------------|-------------|---------------|----------|------------|----------------|---------------|
| Field      | CLK Output | Int Enable | Int Act Low | TTL Threshold | Reserved | Open Drain | Pull-up Enable | Output Enable |
| Read/Write | R/W        | R/W        | R/W         | R/W           | –        | R/W        | R/W            | R/W           |
| Default    | 0          | 0          | 0           | 0             | 0        | 0          | 0              | 0             |

This register controls the operation of the P1.2

**Bit 7** CLK Output  
 0 = The internally selected clock is not sent out onto P1.2 pin  
 1 = When CLK Output is set, the internally selected clock is sent out onto P1.2 pin

**Table 56. P1.3 Configuration (P13CR) [0x10] [R/W]**

| Bit #      | 7        | 6          | 5           | 4          | 3         | 2          | 1              | 0             |
|------------|----------|------------|-------------|------------|-----------|------------|----------------|---------------|
| Field      | Reserved | Int Enable | Int Act Low | 3.3V Drive | High Sink | Open Drain | Pull-up Enable | Output Enable |
| Read/Write | –        | R/W        | R/W         | R/W        | R/W       | R/W        | R/W            | R/W           |
| Default    | 0        | 0          | 0           | 0          | 0         | 0          | 0              | 0             |

This register controls the operation of the P1.3 pin. This register exists in all CYRF69213 parts

The P1.3 GPIO's threshold is always set to TTL

When the SPI hardware is enabled, the output enable and output state of the pin is controlled by the SPI circuitry. When the SPI hardware is disabled, the pin is controlled by the Output Enable bit and the corresponding bit in the P1 data register

Regardless of whether the pin is used as an SPI or GPIO pin the Int Enable, Int act Low, 3.3V Drive, High Sink, Open Drain, and Pull-up Enable control the behavior of the pin

The 50-mA sink drive capability is only available in the CY7C638xx.

**Table 57. P1.4–P1.6 Configuration (P14CR–P16CR) [0x11–0x13] [R/W]**

| Bit #      | 7       | 6          | 5           | 4          | 3         | 2          | 1              | 0             |
|------------|---------|------------|-------------|------------|-----------|------------|----------------|---------------|
| Field      | SPI Use | Int Enable | Int Act Low | 3.3V Drive | High Sink | Open Drain | Pull-up Enable | Output Enable |
| Read/Write | R/W     | R/W        | R/W         | R/W        | R/W       | R/W        | R/W            | R/W           |
| Default    | 0       | 0          | 0           | 0          | 0         | 0          | 0              | 0             |

These registers control the operation of pins P1.4–P1.6, respectively

The P1.4–P1.6 GPIO's threshold is always set to TTL

When the SPI hardware is enabled, pins that are configured as SPI Use have their output enable and output state controlled by the SPI circuitry. When the SPI hardware is disabled or a pin has its SPI Use bit clear, the pin is controlled by the Output Enable bit and the corresponding bit in the P1 data register

Regardless of whether any pin is used as an SPI or GPIO pin the Int Enable, Int act Low, 3.3V Drive, High Sink, Open Drain, and Pull-up Enable control the behavior of the pin

Bit 7

SPI Use

0 = Disable the SPI alternate function. The pin is used as a GPIO

1 = Enable the SPI function. The SPI circuitry controls the output of the pin

**Important Note for Comm Modes 01 or 10 (SPI Master or SPI Slave, see Table 61)**

When configured for SPI (SPI Use = 1 and Comm Modes [1:0] = SPI Master or SPI Slave mode), the input/output direction of pins P1.3, P1.5, and P1.6 is set automatically by the SPI logic. However, pin P1.4's input/output direction is NOT automatically set; it must be explicitly set by firmware. For SPI Master mode, pin P1.4 must be configured as an output; for SPI Slave mode, pin P1.4 must be configured as an input

**Table 58. P1.7 Configuration (P17CR) [0x14] [R/W]**

| Bit #      | 7        | 6          | 5           | 4          | 3         | 2          | 1              | 0             |
|------------|----------|------------|-------------|------------|-----------|------------|----------------|---------------|
| Field      | Reserved | Int Enable | Int Act Low | TTL Thresh | High Sink | Open Drain | Pull-up Enable | Output Enable |
| Read/Write | –        | R/W        | R/W         | R/W        | R/W       | R/W        | R/W            | R/W           |
| Default    | 0        | 0          | 0           | 0          | 0         | 0          | 0              | 0             |

This register controls the operation of pin P1.7. This register only exists in CY7C638xx

The 50-mA sink drive capability is only available in the CY7C638xx. The P1.7 GPIO's threshold is always set to TTL

**Table 59. P2 Configuration (P2CR) [0x15] [R/W]**

| Bit #      | 7        | 6          | 5           | 4          | 3         | 2          | 1              | 0             |
|------------|----------|------------|-------------|------------|-----------|------------|----------------|---------------|
| Field      | Reserved | Int Enable | Int Act Low | TTL Thresh | High Sink | Open Drain | Pull-up Enable | Output Enable |
| Read/Write | –        | R/W        | R/W         | R/W        | R/W       | R/W        | R/W            | R/W           |
| Default    | 0        | 0          | 0           | 0          | 0         | 0          | 0              | 0             |

This register only exists in CY7C638xx. This register controls the operation of pins P2.0–P2.1. In the CY7C638xx, only 8-mA sink drive capability is available on this pin regardless of the setting of the High Sink bit

**GPIO Configurations for Low Power Mode:**

To ensure low power mode, unbonded GPIO pins in CYRF69213 must be placed in a non-floating state. The following assembly code snippet shows how this is achieved. This snippet can be added as a part of the initialization routine.

```
//Code Snippet for addressing unbonded GPIOs

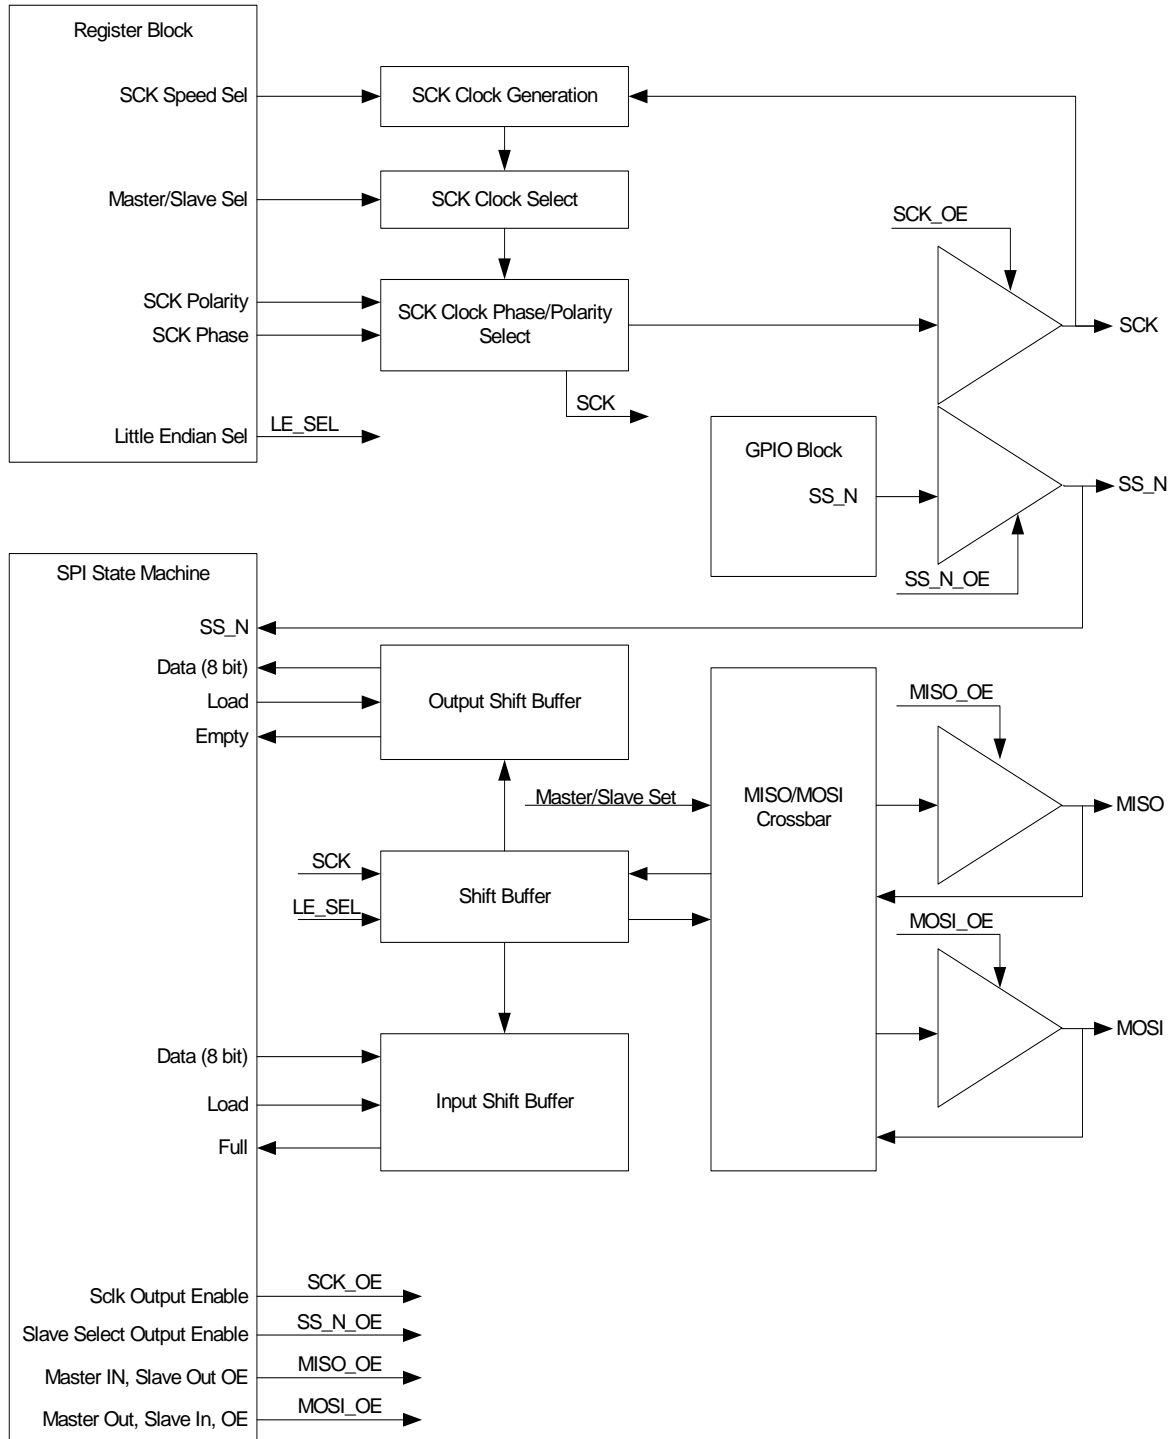

mov A, 00h
mov reg[1Fh],A
mov A, 01h
mov reg[16h],A // Port3 Configuration register - Enable ouptut
mov A, 00h
mov reg[03h],A // Asserting P3.0 and P3.1 outputs to '0'
mov A, 01h
mov reg[05h],A // Port0.0 Configuration register - Enable output
mov reg[07h],A // Port0.2 Configuration register - Enable output
mov reg[0Ah],A // Port0.5 Configuration register - Enable output
mov reg[0Bh],A // Port0.6 Configuration register - Enable output
mov A,reg[00h]
mov A,00h
and A,9Ah
mov reg[00h], A // Asserting outputs '0' to pins in port 1
```

When writing to port 0 , to access GPIOs P0.1,3,4,7 , mask bits 0,2,5,6 .Failing to do so will void the low power

## Serial Peripheral Interface (SPI)

The SPI Master/Slave Interface core logic runs on the SPI clock domain, making its functionality independent of system clock speed. SPI is a four pin serial interface comprised of a clock, an enable and two data pins.

Figure 14. SPI Block Diagram

**SPI Data Register**

**Table 60. SPI Data Register (SPIDATA) [0x3C] [R/W]**

| Bit #      | 7            | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|------------|--------------|-----|-----|-----|-----|-----|-----|-----|
| Field      | SPIData[7:0] |     |     |     |     |     |     |     |
| Read/Write | R/W          | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Default    | 0            | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

When read, this register returns the contents of the receive buffer. When written, it loads the transmit holding register

**Bits 7:0** SPI Data [7:0]

When an interrupt occurs to indicate to firmware that a byte of receive data is available, or the transmitter holding register is empty, firmware has 7 SPI clocks to manage the buffers—to empty the receiver buffer, or to refill the transmit holding register. Failure to meet this timing requirement will result in incorrect data transfer.

**SPI Configure Register**

**Table 61. SPI Configure Register (SPICR) [0x3D] [R/W]**

| Bit #      | 7    | 6         | 5         | 4   | 3    | 2    | 1           | 0   |
|------------|------|-----------|-----------|-----|------|------|-------------|-----|
| Field      | Swap | LSB First | Comm Mode |     | CPOL | CPHA | SCLK Select |     |
| Read/Write | R/W  | R/W       | R/W       | R/W | R/W  | R/W  | R/W         | R/W |
| Default    | 0    | 0         | 0         | 0   | 0    | 0    | 0           | 0   |

- Bit 7** Swap  
0 = Swap function disabled  
1 = The SPI block swaps its use of SMOSI and SMISO. Among other things, this can be useful in implementing single wire SPI-like communications
- Bit 6** LSB First  
0 = The SPI transmits and receives the MSB (Most Significant Bit) first  
1 = The SPI transmits and receives the LSB (Least Significant Bit) first.
- Bits 5:4** Comm Mode [1:0]  
0 0: All SPI communication disabled  
0 1: SPI master mode  
1 0: SPI slave mode  
1 1: Reserved
- Bit 3** CPOL  
This bit controls the SPI clock (SCLK) idle polarity  
0 = SCLK idles low  
1 = SCLK idles high
- Bit 2** CPHA  
The Clock Phase bit controls the phase of the clock on which data is sampled. [Table 62](#) shows the timing for the various combinations of LSB First, CPOL, and CPHA
- Bits 1:0** SCLK Select  
This field selects the speed of the master SCLK. When in master mode, SCLK is generated by dividing the base CPUCCLK

**Important Note for Comm Modes 01b or 10b (SPI Master or SPI Slave):**

When configured for SPI, (SPI Use = 1—[Table 57](#)), the input/output direction of pins P1.3, P1.5, and P1.6 is set automatically by the SPI logic. However, pin P1.4's input/output direction is NOT automatically set; it must be explicitly set by firmware. For SPI Master mode, pin P1.4 must be configured as an output; for SPI Slave mode, pin P1.4 must be configured as an input

Table 62. SPI Mode Timing vs. LSB First, CPOL and CPHA

| LSB First | CPHA | CPOL | Diagram  |
|-----------|------|------|--|
| 0         | 0    | 0    |  <p>SCLK</p> <p>SSEL</p> <p>DATA X MSB Bit 7 Bit 6 Bit 5 Bit 4 Bit 3 Bit 2 LSB X</p>   |

**Table 63. SPI SCLK Frequency**

| SCLK Select | CPUCLK Divisor | SCLK Frequency when CPUCLK = |         |
|-------------|----------------|------------------------------|---------|
|             |                | 12 MHz                       | 24 MHz  |
| 00          | 6              | 2 MHz                        | 4 MHz   |
| 01          | 12             | 1 MHz                        | 2 MHz   |
| 10          | 48             | 250 KHz                      | 500 KHz |
| 11          | 96             | 125 KHz                      | 250 KHz |

**Timer Registers**

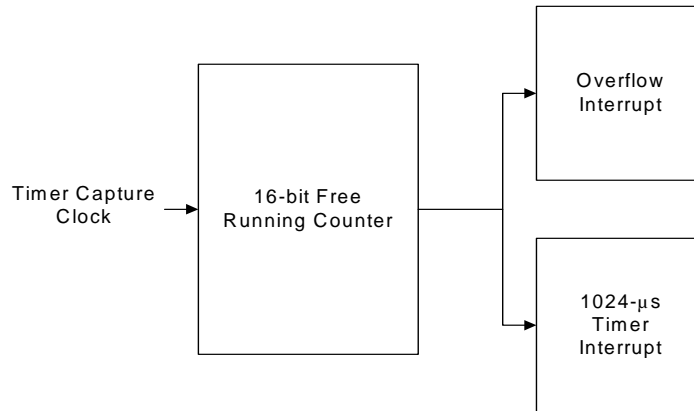

All timer functions of the CYRF69213 are provided by a single timer block. The timer block is asynchronous from the CPU clock.

**Registers**

*Free-Running Counter*

The 16-bit free-running counter is clocked by a 4/6-MHz source. It can be read in software for use as a general-purpose time base. When the low order byte is read, the high order byte is registered. Reading the high order byte reads this register allowing the CPU to read the 16-bit value atomically (loads all bits at one time). The free-running timer generates an interrupt at a 1024-μs rate. It can also generate an interrupt when the free-running counter overflow occurs—every 16.384 ms. This allows extending the length of the timer in software.

**Figure 15. 16-Bit Free-Running Counter Block Diagram**

**Table 64. Free-Running Timer Low-Order Byte (FRTMRL) [0x20] [R/W]**

| Bit #      | 7                        | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|------------|--------------------------|-----|-----|-----|-----|-----|-----|-----|
| Field      | Free-running Timer [7:0] |     |     |     |     |     |     |     |
| Read/Write | R/W                      | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Default    | 0                        | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

**Bits 7:0** Free-running Timer [7:0]

This register holds the low-order byte of the 16-bit free-running timer. Reading this register causes the high-order byte to be moved into a holding register allowing an automatic read of all 16 bits simultaneously. For reads, the actual read occurs in the cycle when the low order is read. For writes, the actual time the write occurs is the cycle when the high order is written

When reading the free-running timer, the low-order byte should be read first and the high-order second. When writing, the low-order byte should be written first then the high-order byte

**Table 65. Free-Running Timer High-Order Byte (FRTMRH) [0x21] [R/W]**

| Bit #      | 7                         | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|------------|---------------------------|-----|-----|-----|-----|-----|-----|-----|
| Field      | Free-running Timer [15:8] |     |     |     |     |     |     |     |
| Read/Write | R/W                       | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Default    | 0                         | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

**Bits 7:0** Free-running Timer [15:8]

When reading the free-running timer, the low-order byte should be read first and the high-order second. When writing, the low-order byte should be written first then the high-order byte

**Table 66. Programmable Interval Timer Low (PITMRL) [0x26] [R]**

| Bit #      | 7                         | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|------------|---------------------------|---|---|---|---|---|---|---|
| Field      | Prog Interval Timer [7:0] |   |   |   |   |   |   |   |
| Read/Write | R                         | R | R | R | R | R | R | R |
| Default    | 0                         | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

**Bits 7:0** Prog Interval Timer [7:0]

This register holds the low-order byte of the 12-bit programmable interval timer. Reading this register causes the high-order byte to be moved into a holding register allowing an automatic read of all 12 bits simultaneously

**Table 67. Programmable Interval Timer High (PITMRH) [0x27] [R]**

| Bit #      | 7        | 6 | 5 | 4 | 3                          | 2 | 1 | 0 |
|------------|----------|---|---|---|----------------------------|---|---|---|
| Field      | Reserved |   |   |   | Prog Interval Timer [11:8] |   |   |   |
| Read/Write | –        | – | – | – | R                          | R | R | R |
| Default    | 0        | 0 | 0 | 0 | 0                          | 0 | 0 | 0 |

**Bits 7:4** Reserved

**Bits 3:0** Prog Internal Timer [11:8]

This register holds the high-order nibble of the 12-bit programmable interval timer. Reading this register returns the high-order nibble of the 12-bit timer at the instant that the low-order byte was last read

**Table 68. Programmable Interval Reload Low (PIRL) [0x28] [R/W]**

| Bit #      | 7                   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|------------|---------------------|-----|-----|-----|-----|-----|-----|-----|
| Field      | Prog Interval [7:0] |     |     |     |     |     |     |     |
| Read/Write | R/W                 | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Default    | 0                   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

**Bits 7:0** Prog Interval [7:0]

This register holds the lower 8 bits of the timer. While writing into the 12-bit reload register, write lower byte first then the higher nibble

**Table 69. Programmable Interval Reload High (PIRH) [0x29] [R/W]**

| Bit #      | 7        | 6 | 5 | 4 | 3                   | 2   | 1   | 0   |
|------------|----------|---|---|---|---------------------|-----|-----|-----|
| Field      | Reserved |   |   |   | Prog Interval[11:8] |     |     |     |
| Read/Write | –        | – | – | – | R/W                 | R/W | R/W | R/W |
| Default    | 0        | 0 | 0 | 0 | 0                   | 0   | 0   | 0   |

**Bits 7:4** Reserved

**Bits 3:0** Prog Interval [11:8]

This register holds the higher 4 bits of the timer. While writing into the 12-bit reload register, write lower byte first then the higher nibble

Figure 16. 16-Bit Free-Running Counter Loading Timing Diagram

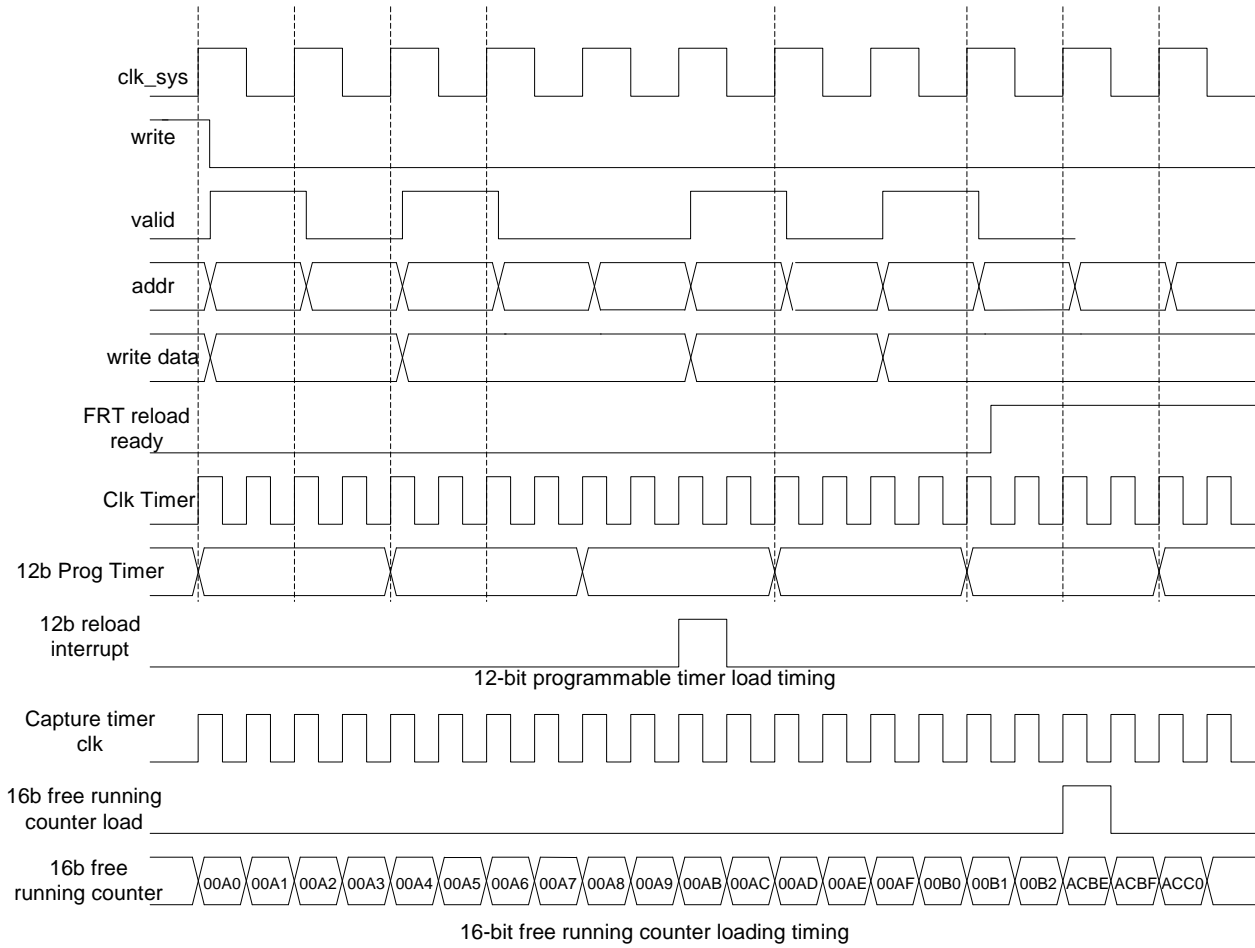

Figure 17. Memory Mapped Registers Read/Write Timing Diagram

## Interrupt Controller

The interrupt controller and its associated registers allow the user's code to respond to an interrupt from almost every functional block in the CYRF69213 devices. The registers associated with the interrupt controller allow interrupts to be disabled either globally or individually. The registers also provide a mechanism by which a user may clear all pending and posted interrupts, or clear individual posted or pending interrupts.

The following table lists all interrupts and the priorities that are available in the CYRF69213.

**Table 70. Interrupt Numbers, Priorities, Vectors**

| Interrupt Priority | Interrupt Address | Name                           |
|--------------------|-------------------|--------------------------------|
| 0                  | 0000h             | Reset                          |
| 1                  | 0004h             | POR/LVD                        |
| 2                  | 0008h             | INT0                           |
| 3                  | 000Ch             | SPI Transmitter Empty          |

### Architectural Description

An interrupt is posted when its interrupt conditions occur. This results in the flip-flop in [Figure 18](#) clocking in a '1'. The interrupt will remain posted until the interrupt is taken or until it is cleared by writing to the appropriate INT\_CLRx register.

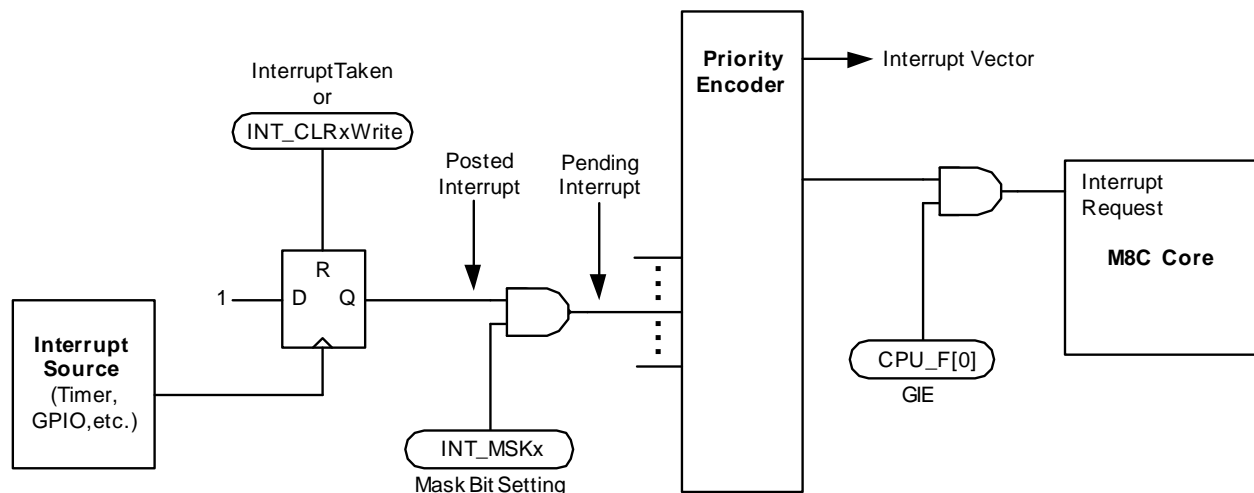

A posted interrupt is not pending unless it is enabled by setting its interrupt mask bit (in the appropriate INT\_MSKx register). All pending interrupts are processed by the Priority Encoder to determine the highest priority interrupt which will be taken by the M8C if the Global Interrupt Enable bit is set in the CPU\_F register.

Disabling an interrupt by clearing its interrupt mask bit (in the INT\_MSKx register) does not clear a posted interrupt, nor does it prevent an interrupt from being posted. It simply prevents a posted interrupt from becoming pending.

Nested interrupts can be accomplished by re-enabling interrupts inside an interrupt service routine. To do this, set the IE bit in the Flag Register.

A block diagram of the CYRF69213 Interrupt Controller is shown in [Figure 18](#).

**Figure 18. Interrupt Controller Block Diagram**

### Interrupt Processing

The sequence of events that occur during interrupt processing is as follows:

1. An interrupt becomes active, either because:
  - a. The interrupt condition occurs (for example, a timer expires).
  - b. A previously posted interrupt is enabled through an update of an interrupt mask register.
  - c. An interrupt is pending and GIE is set from 0 to 1 in the CPU Flag register.
  - d. The GPIO interrupts are edge triggered.
2. The current executing instruction finishes.
3. The internal interrupt is dispatched, taking 13 cycles. During this time, the following actions occur:
  - a. The MSB and LSB of Program Counter and Flag registers (CPU\_PC and CPU\_F) are stored onto the program stack by an automatic CALL instruction (13 cycles) generated during the interrupt acknowledge process.
  - b. The PCH, PCL, and Flag register (CPU\_F) are stored onto the program stack (in that order) by an automatic CALL instruction (13 cycles) generated during the interrupt acknowledge process.
  - c. The CPU\_F register is then cleared. Since this clears the GIE bit to 0, additional interrupts are temporarily disabled
  - d. The PCH (PC[15:8]) is cleared to zero.
  - e. The interrupt vector is read from the interrupt controller and its value placed into PCL (PC[7:0]). This sets the program counter to point to the appropriate address in the interrupt table (for example, 0004h for the POR/LVD interrupt).
4. Program execution vectors to the interrupt table. Typically, a LJMP instruction in the interrupt table sends execution to the user's Interrupt Service Routine (ISR) for this interrupt.
5. The ISR executes. Note that interrupts are disabled since GIE = 0. In the ISR, interrupts can be re-enabled if desired by setting GIE = 1 (care must be taken to avoid stack overflow).

6. The ISR ends with a RETI instruction which restores the Program Counter and Flag registers (CPU\_PC and CPU\_F). The restored Flag register re-enables interrupts, since GIE = 1 again.
7. Execution resumes at the next instruction, after the one that occurred before the interrupt. However, if there are more pending interrupts, the subsequent interrupts will be processed before the next normal program instruction.

### Interrupt Latency

The time between the assertion of an enabled interrupt and the start of its ISR can be calculated from the following equation.

Latency = Time for current instruction to finish + Time for internal interrupt routine to execute + Time for LJMP instruction in interrupt table to execute.

For example, if the 5-cycle JMP instruction is executing when an interrupt becomes active, the total number of CPU clock cycles before the ISR begins would be as follows:

$$(1 \text{ to } 5 \text{ cycles for JMP to finish}) + (13 \text{ cycles for interrupt routine}) + (7 \text{ cycles for LJMP}) = 21 \text{ to } 25 \text{ cycles.}$$

In the example above, at 24 MHz, 25 clock cycles take 1.042 μs.

### Interrupt Registers

The Interrupt Registers are discussed in the following sections.

#### Interrupt Clear Register

The Interrupt Clear Registers (INT\_CLRx) are used to enable the individual interrupt sources' ability to clear posted interrupts.

When an INT\_CLRx register is read, any bits that are set indicates an interrupt has been posted for that hardware resource. Therefore, reading these registers gives the user the ability to determine all posted interrupts.

**Table 71. Interrupt Clear 0 (INT\_CLR0) [0xDA] [R/W]**

| Bit #      | 7           | 6           | 5    | 4           | 3           | 2            | 1    | 0       |
|------------|-------------|-------------|------|-------------|-------------|--------------|------|---------|
| Field      | GPIO Port 1 | Sleep Timer | INT1 | GPIO Port 0 | SPI Receive | SPI Transmit | INT0 | POR/LVD |
| Read/Write | R/W         | R/W         | R/W  | R/W         | R/W         | R/W          | R/W  | R/W     |
| Default    | 0           | 0           | 0    | 0           | 0           | 0            | 0    | 0       |

When reading this register,

0 = There's no posted interrupt for the corresponding hardware

1 = Posted interrupt for the corresponding hardware present

Writing a '0' to the bits will clear the posted interrupts for the corresponding hardware. Writing a '1' to the bits and to the ENSWINT (Bit 7 of the INT\_MSK3 Register) will post the corresponding hardware interrupt

**Table 72. Interrupt Clear 1 (INT\_CLR1) [0xDB] [R/W]**

| Bit #      | 7        | 6                   | 5          | 4          | 3         | 2       | 1       | 0       |
|------------|----------|---------------------|------------|------------|-----------|---------|---------|---------|
| Field      | Reserved | Prog Interval Timer | 1-ms Timer | USB Active | USB Reset | USB EP2 | USB EP1 | USB EP0 |
| Read/Write | R/W      | R/W                 | R/W        | R/W        | R/W       | R/W     | R/W     | R/W     |
| Default    | 0        | 0                   | 0          | 0          | 0         | 0       | 0       | 0       |

When reading this register,

0 = There's no posted interrupt for the corresponding hardware

1 = Posted interrupt for the corresponding hardware present

Writing a '0' to the bits will clear the posted interrupts for the corresponding hardware. Writing a '1' to the bits AND to the ENSWINT (Bit 7 of the INT\_MSK3 Register) will post the corresponding hardware interrupt

Bit 7 Reserved

**Table 73. Interrupt Clear 2 (INT\_CLR2) [0xDC] [R/W]**

| Bit #      | 7        | 6        | 5        | 4           | 3        | 2    | 1                   | 0        |
|------------|----------|----------|----------|-------------|----------|------|---------------------|----------|

| Read/Write | R/W      | R/W      | R/W      | R/W         | R/W      | R/W  | R/W                 | R/W      |
| Default    | 0        | 0        | 0        | 0           | 0        | 0    | 0                   | 0        |

When reading this register,

0 = There's no posted interrupt for the corresponding hardware

1 = Posted interrupt for the corresponding hardware present

Writing a '0' to the bits will clear the posted interrupts for the corresponding hardware. Writing a '1' to the bits AND to the ENSWINT (Bit 7 of the INT\_MSK3 Register) will post the corresponding hardware interrupt

Bits 7,6,5,3,0Reserved

### Interrupt Mask Registers

The Interrupt Mask Registers (INT\_MSKx) are used to enable the individual interrupt sources' ability to create pending interrupts.

There are four Interrupt Mask Registers (INT\_MSK0, INT\_MSK1, INT\_MSK2, and INT\_MSK3), which may be referred to in general as INT\_MSKx. If cleared, each bit in an INT\_MSKx register prevents a posted interrupt from becoming a pending interrupt (input to the priority encoder). However, an interrupt can still post even if its mask bit is zero. All INT\_MSKx bits are independent of all other INT\_MSKx bits.

If an INT\_MSKx bit is set, the interrupt source associated with that mask bit may generate an interrupt that will become a pending interrupt.

The Enable Software Interrupt (ENSWINT) bit in INT\_MSK3[7] determines the way an individual bit value written to an INT\_CLRx register is interpreted. When is cleared, writing 1's to an INT\_CLRx register has no effect. However, writing 0's to an INT\_CLRx register, when ENSWINT is cleared, will cause the corresponding interrupt to clear. If the ENSWINT bit is set, any 0's written to the INT\_CLRx registers are ignored. However, 1's written to an INT\_CLRx register, while ENSWINT is set, will cause an interrupt to post for the corresponding interrupt.

Software interrupts can aid in debugging interrupt service routines by eliminating the need to create system level interactions that are sometimes necessary to create a hardware-only interrupt.

**Table 74. Interrupt Mask 3 (INT\_MSK3) [0xDE] [R/W]**

| Bit #      | 7       | 6        | 5 | 4 | 3 | 2 | 1 | 0 |
|------------|---------|----------|---|---|---|---|---|---|
| Field      | ENSWINT | Reserved |   |   |   |   |   |   |
| Read/Write | R/W     | –        | – | – | – | – | – | – |
| Default    | 0       | 0        | 0 | 0 | 0 | 0 | 0 | 0 |

Bit 7 Enable Software Interrupt (ENSWINT)

0 = Disable. Writing 0's to an INT\_CLRx register, when ENSWINT is cleared, will cause the corresponding interrupt to clear

1 = Enable. Writing 1's to an INT\_CLRx register, when ENSWINT is set, will cause the corresponding interrupt to post

Bits 6:0 Reserved

*Interrupt Vector Clear Register*

**Table 78. Interrupt Vector Clear Register (INT\_VC) [0xE2] [R/W]**

| Bit #      | 7                       | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|------------|-------------------------|-----|-----|-----|-----|-----|-----|-----|
| Field      | Pending Interrupt [7:0] |     |     |     |     |     |     |     |
| Read/Write | R/W                     | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Default    | 0                       | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

The Interrupt Vector Clear Register (INT\_VC) holds the interrupt vector for the highest priority pending interrupt when read, and when written will clear all pending interrupts

- Bits 7:0** Pending Interrupt [7:0]  
8-bit data value holds the interrupt vector for the highest priority pending interrupt. Writing to this register will clear all pending interrupts

## USB Transceiver

### USB Transceiver Configuration

**Table 79. USB Transceiver Configure Register (USBXCR) [0x74] [R/W]**

| Bit #      | 7                  | 6        | 5 | 4 | 3 | 2 | 1 | 0               |
|------------|--------------------|----------|---|---|---|---|---|-----------------|
| Field      | USB Pull-up Enable | Reserved |   |   |   |   |   | USB Force State |
| Read/Write | R/W                | –        | – | – | – | – | – | R/W             |
| Default    | 0                  | 0        | 0 | 0 | 0 | 0 | 0 | 0               |

**Bit 7** USB Pull-up Enable  
 0 = Disable the pull-up resistor on D–  
 1 = Enable the pull-up resistor on D–. This pull-up is to V<sub>CC</sub> IF VREG is not enabled or to the internally generated 3.3V when VREG is enabled. This bit should be cleared in sleep mode.

**Bits 6:1** Reserved

**Bit 0** USB Force State  
 This bit allows the state of the USB IO pins DP and D+ to be forced to a state while USB is enabled  
 0 = Disable USB Force State  
 1 = Enable USB Force State. Allows the D– and D+ pins to be controlled by P1.1 and P1.0 respectively when the USBIO is in USB mode. Refer to [Table 48](#) for more information

**Note** The USB transceiver has a dedicated 3.3V regulator for USB signalling purposes and to provide for the 1.5K D– pull up. Unlike the other 3.3V regulator, this regulator cannot be controlled/accessed by firmware. When the device is suspended, this regulator is disabled along with the bandgap (which provides the reference voltage to the regulator) and the D– line is pulled up to 5V through an alternate 6.5K resistor. During wakeup following a suspend, the band gap and the regulator are switched on in any order. Under an extremely rare case when the device wakes up following a bus reset condition and the voltage regulator and the band gap turn on in that particular order, there is possibility of a glitch/low pulse occurring on the D– line. The host can misinterpret this as a deattach condition. This condition, although rare, can be avoided by keeping the bandgap circuitry enabled during sleep. This is achieved by setting the ‘No Buzz’ bit, bit[5] in the OSC\_CR0 register. This is an issue only if the device is put to sleep during a bus reset condition

### VREG Control

**Table 80. VREG Control Register (VREGCR) [0x73] [R/W]**

| Bit #      | 7        | 6 | 5 | 4 | 3 | 2 | 1          | 0           |
|------------|----------|---|---|---|---|---|------------|-------------|
| Field      | Reserved |   |   |   |   |   | Keep Alive | VREG Enable |
| Read/Write | –        | – | – | – | – | – | R/W        | R/W         |
| Default    | 0        | 0 | 0 | 0 | 0 | 0 | 0          | 0           |

**Bits 7:2** Reserved

**Bit 1** Keep Alive  
 Keep Alive when set allows the voltage regulator to source up to 20 μA of current when voltage regulator is disabled, P12CR[0],P12CR[7] should be cleared.  
 0 = Disabled  
 1 = Enabled

**Bit 0** VREG Enable  
 This bit turns on the 3.3V voltage regulator. The voltage regulator only functions within specifications when V<sub>CC</sub> is above 4.35V. This block should not be enabled when V<sub>CC</sub> is below 4.35V—although no damage or irregularities will occur if it is enabled below 4.35V  
 0 = Disable the 3.3V voltage regulator output on the VREG/P1.2 pin  
 1 = Enable the 3.3V voltage regulator output on the VREG/P1.2 pin. GPIO functionality of P1.2 is disabled

**Note** Use of the alternate drive on pins P1.3–P1.6 requires that the VREG Enable bit be set to enable the regulator and provide the alternate voltage

## USB Serial Interface Engine (SIE)

The SIE allows the microcontroller to communicate with the USB host at low-speed data rates (1.5 Mbps). The SIE simplifies the interface between the microcontroller and USB by incorporating hardware that handles the following USB bus activity independently of the microcontroller:

- Translating the encoded received data and formatting the data to be transmitted on the bus
- CRC checking and generation. Flagging the microcontroller if errors exist during transmission
- Address checking. Ignoring the transactions not addressed to the device
- Sending appropriate ACK/NAK/STALL handshakes

- Identifying token type (SETUP, IN, or OUT). Setting the appropriate token bit once a valid token is received
- Placing valid received data in the appropriate endpoint FIFOs
- Sending and updating the data toggle bit (Data1/0)
- Bit stuffing/unstuffing.

Firmware is required to handle the rest of the USB interface with the following tasks:

- Coordinate enumeration by decoding USB device requests
- Fill and empty the FIFOs
- Suspend/Resume coordination
- Verify and select Data toggle values

## USB Device

Table 81. USB Device Address (USBCR) [0x40] [R/W]

| Bit #      | 7          | 6                   | 5   | 4   | 3   | 2   | 1   | 0   |
|------------|------------|---------------------|-----|-----|-----|-----|-----|-----|
| Field      | USB Enable | Device Address[6:0] |     |     |     |     |     |     |
| Read/Write | R/W        | R/W                 | R/W | R/W | R/W | R/W | R/W | R/W |
| Default    | 0          | 0                   | 0   | 0   | 0   | 0   | 0   | 0   |

The content of this register is cleared when a USB Bus Reset condition occurs

- Bit 7** USB Enable  
 This bit must be enabled by firmware before the serial interface engine (SIE) will respond to USB traffic at the address specified in Device Address [6:0]. When this bit is cleared, the USB transceiver enters power-down state. User's firmware should clear this bit prior to entering sleep mode to save power  
 0 = Disable USB device address and put the USB transceiver into power-down state  
 1 = Enable USB device address and put the USB transceiver into normal operating mode

- Bits 6:0** Device Address [6:0]  
 These bits must be set by firmware during the USB enumeration process (for example, SetAddress) to the non-zero address assigned by the USB host

**Table 82. Endpoint 0, 1, and 2 Count (EP0CNT–EP2CNT) [0x41, 0x43, 0x45] [R/W]**

| Bit #      | 7           | 6          | 5        | 4   | 3               | 2   | 1   | 0   |
|------------|-------------|------------|----------|-----|-----------------|-----|-----|-----|
| Field      | Data Toggle | Data Valid | Reserved |     | Byte Count[3:0] |     |     |     |
| Read/Write | R/W         | R/W        | R/W      | R/W | R/W             | R/W | R/W | R/W |
| Default    | 0           | 0          | 0        | 0   | 0               | 0   | 0   | 0   |

**Bit 7** Data Toggle  
 This bit selects the DATA packet's toggle state. For IN transactions, firmware must set this bit to the select the transmitted Data Toggle. For OUT or SETUP transactions, the hardware sets this bit to the state of the received Data Toggle bit.  
 0 = DATA0  
 1 = DATA1

**Bit 6** Data Valid  
 This bit is used for OUT and SETUP tokens only. This bit is cleared to '0' if CRC, bitstuff, or PID errors have occurred. This bit does not update for some endpoint mode settings  
 0 = Data is invalid. If enabled, the endpoint interrupt will occur even if invalid data is received  
 1 = Data is valid

**Bits 5:4** Reserved

**Bits 3:0** Byte Count Bit [3:0]  
 Byte Count Bits indicate the number of data bytes in a transaction: For IN transactions, firmware loads the count with the number of bytes to be transmitted to the host from the endpoint FIFO. Valid values are 0 to 8 inclusive. For OUT or SETUP transactions, the count is updated by hardware to the number of data bytes received, plus 2 for the CRC bytes. Valid values are 2–10 inclusive.

For Endpoint 0 Count Register, whenever the count updates from a SETUP or OUT transaction, the count register locks and cannot be written by the CPU. Reading the register unlocks it. This prevents firmware from overwriting a status update on it

**Endpoint 0 Mode**

Because both firmware and the SIE are allowed to write to the Endpoint 0 Mode and Count Registers the SIE provides an interlocking mechanism to prevent accidental overwriting of data.

When the SIE writes to these registers they are locked and the processor cannot write to them until after it has read them. Writing to this register clears the upper four bits regardless of the value written.

**Table 83. Endpoint 0 Mode (EP0MODE) [0x44] [R/W]**

| Bit #      | 7              | 6           | 5            | 4           | 3         | 2   | 1   | 0   |
|------------|----------------|-------------|--------------|-------------|-----------|-----|-----|-----|
| Field      | Setup Received | IN Received | OUT Received | ACK'd Trans | Mode[3:0] |     |     |     |
| Read/Write | R/C[3]         | R/C[3]      | R/C[3]       | R/C[3]      | R/W       | R/W | R/W | R/W |
| Default    | 0              | 0           | 0            | 0           | 0         | 0   | 0   | 0   |

- Bit 7**      SETUP Received  
 This bit is set by hardware when a valid SETUP packet is received. It is forced HIGH from the start of the data packet phase of the SETUP transactions until the end of the data phase of a control write transfer and cannot be cleared during this interval. While this bit is set to '1', the CPU cannot write to the EP0 FIFO. This prevents firmware from overwriting an incoming SETUP transaction before firmware has a chance to read the SETUP data  
 This bit is cleared by any non-locked writes to the register  
 0 = No SETUP received  
 1 = SETUP received
- Bit 6**      IN Received  
 This bit, when set, indicates a valid IN packet has been received. This bit is updated to '1' after the host acknowledges an IN data packet. When clear, it indicates that either no IN has been received or that the host didn't acknowledge the IN data by sending an ACK handshake  
 This bit is cleared by any non-locked writes to the register.  
 0 = No IN received  
 1 = IN received
- Bit 5**      OUT Received  
 This bit, when set, indicates a valid OUT packet has been received and ACKed. This bit is updated to '1' after the last received packet in an OUT transaction. When clear, it indicates no OUT received  
 This bit is cleared by any non-locked writes to the register  
 0 = No OUT received  
 1 = OUT received
- Bit 4**      ACK'd Transaction  
 The ACK'd transaction bit is set whenever the SIE engages in a transaction to the register's endpoint that completes with a ACK packet  
 This bit is cleared by any non-locked writes to the register  
 1 = The transaction completes with an ACK  
 0 = The transaction does not complete with an ACK
- Bits 3:0**    Mode [3:0]  
 The endpoint modes determine how the SIE responds to USB traffic that the host sends to the endpoint. The mode controls how the USB SIE responds to traffic and how the USB SIE will change the mode of that endpoint as a result of host packets to the endpoint

**Table 84. Endpoint 1 and 2 Mode (EP1MODE – EP2MODE) [0x45, 0x46] [R/W]**

| Bit #      | 7     | 6        | 5              | 4                 | 3         | 2   | 1   | 0   |
|------------|-------|----------|----------------|-------------------|-----------|-----|-----|-----|
| Field      | Stall | Reserved | NAK Int Enable | ACK'd Transaction | Mode[3:0] |     |     |     |
| Read/Write | R/W   | R/W      | R/W            | R/C (Note 3)      | R/W       | R/W | R/W | R/W |
| Default    | 0     | 0        | 0              | 0                 | 0         | 0   | 0   | 0   |

- Bit 7** Stall  
When this bit is set the SIE will stall an OUT packet if the Mode Bits are set to ACK-OUT, and the SIE will stall an IN packet if the mode bits are set to ACK-IN. This bit must be clear for all other modes
- Bit 6** Reserved
- Bit 5** NAK Int Enable  
This bit, when set, causes an endpoint interrupt to be generated even when a transfer completes with a NAK. Unlike enCoRe, CYRF69213 family members do not generate an endpoint interrupt under these conditions unless this bit is set  
0 = Disable interrupt on NAK'd transactions  
1 = Enable interrupt on NAK'd transaction
- Bit 4** ACK'd Transaction  
The ACK'd transaction bit is set whenever the SIE engages in a transaction to the register's endpoint that completes with an ACK packet  
This bit is cleared by any writes to the register  
0 = The transaction does not complete with an ACK  
1 = The transaction completes with an ACK
- Bits 3:0** Mode [3:0]  
The endpoint modes determine how the SIE responds to USB traffic that the host sends to the endpoint. The mode controls how the USB SIE responds to traffic and how the USB SIE will change the mode of that endpoint as a result of host packets to the endpoint.

**Note** When the SIE writes to the EP1MODE or the EP2MODE register it blocks firmware writes to the EP2MODE or the EP1MODE registers, respectively (if both writes occur in the same clock cycle). This is because the design employs only one common 'update' signal for both EP1MODE and EP2MODE registers. Thus, when SIE writes to the EP1MODE register, the update signal is set and this prevents firmware writes to EP2MODE register. SIE writes to the endpoint mode registers have higher priority than firmware writes. This mode register write block situation can put the endpoints in incorrect modes. Firmware must read the EP1/2MODE registers immediately following a firmware write and rewrite if the value read is incorrect

**Endpoint Data Buffers**

The three data buffers are used to hold data for both IN and OUT transactions. Each data buffer is 8 bytes long. The reset values of the Endpoint Data Registers are unknown. Unlike past enCoRe parts the USB data buffers are only accessible in the IO space of the processor.

**Table 85. Endpoint 0 Data (EP0DATA) [0x50-0x57] [R/W]**

| Bit #      | 7                            | 6       | 5       | 4       | 3       | 2       | 1       | 0       |
|------------|------------------------------|---------|---------|---------|---------|---------|---------|---------|
| Field      | Endpoint 0 Data Buffer [7:0] |         |         |         |         |         |         |         |
| Read/Write | R/W                          | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     |
| Default    | Unknown                      | Unknown | Unknown | Unknown | Unknown | Unknown | Unknown | Unknown |

The Endpoint 0 buffer is comprised of 8 bytes located at address 0x50 to 0x57

**Table 86. Endpoint 1 Data (EP1DATA) [0x58-0x5F] [R/W]**

| Bit #      | 7                            | 6       | 5       | 4       | 3       | 2       | 1       | 0       |
|------------|------------------------------|---------|---------|---------|---------|---------|---------|---------|
| Field      | Endpoint 1 Data Buffer [7:0] |         |         |         |         |         |         |         |
| Read/Write | R/W                          | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     |
| Default    | Unknown                      | Unknown | Unknown | Unknown | Unknown | Unknown | Unknown | Unknown |

The Endpoint 1buffer is comprised of 8 bytes located at address 0x58 to 0x5F

**Table 87. Endpoint 2 Data (EP2DATA) [0x60-0x67] [R/W]**

| Bit #      | 7                            | 6       | 5       | 4       | 3       | 2       | 1       | 0       |
|------------|------------------------------|---------|---------|---------|---------|---------|---------|---------|
| Field      | Endpoint 2 Data Buffer [7:0] |         |         |         |         |         |         |         |
| Read/Write | R/W                          | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     |
| Default    | Unknown                      | Unknown | Unknown | Unknown | Unknown | Unknown | Unknown | Unknown |

The Endpoint 2 buffer is comprised of 8 bytes located at address 0x60 to 0x67

**USB Mode Tables**

| Mode                | Encoding | SETUP  | IN       | OUT    | Comments   |
|---------------------|----------|--------|----------|--------|--|
| DISABLE             | 0000     | Ignore | Ignore   | Ignore | Ignore all USB traffic to this endpoint. Used by Data and Control endpoints                                  |
| NAK IN/OUT          | 0001     | Accept | NAK      | NAK    | NAK IN and OUT token. Control endpoint only  |
| STATUS OUT ONLY     | 0010     | Accept | STALL    | Check  | STALL IN and ACK zero byte OUT. Control endpoint only  |
| STALL IN/OUT        | 0011     | Accept | STALL    | STALL  | STALL IN and OUT token. Control endpoint only  |
| STATUS IN ONLY      | 0110     | Accept | TX0 byte | STALL  | STALL OUT and send zero byte data for IN token. Control endpoint only  |
| ACK OUT – STATUS IN | 1011     | Accept | TX0 byte | ACK    | ACK the OUT token or send zero byte data for IN token. Control endpoint only                                 |
| ACK IN – STATUS OUT | 1111     | Accept | TX Count | Check  | Respond to IN data or Status OUT. Control endpoint only  |
|                     |          |        |          |        |  |
| NAK OUT             | 1000     | Ignore | Ignore   | NAK    | Send NAK handshake to OUT token. Data endpoint only  |
| ACK OUT (STALL = 0) | 1001     | Ignore | Ignore   | ACK    | This mode is changed by the SIE to mode 1000 on issuance of ACK handshake to an OUT. Data endpoint only      |
| ACK OUT (STALL = 1) | 1001     | Ignore | Ignore   | STALL  | STALL the OUT transfer   |
| NAK IN              | 1100     | Ignore | NAK      | Ignore | Send NAK handshake for IN token. Data endpoint only  |
| ACK IN (STALL = 0)  | 1101     | Ignore | TX Count | Ignore | This mode is changed by the SIE to mode 1100 after receiving ACK handshake to an IN data. Data endpoint only |
| ACK IN (STALL = 1)  | 1101     | Ignore | STALL    | Ignore | STALL the IN transfer. Data endpoint only  |
|                     |          |        |          |        |  |
| Reserved            | 0101     | Ignore | Ignore   | Ignore | These modes are not supported by SIE. Firmware should not use this mode in Control and Data endpoints        |
| Reserved            | 0111     | Ignore | Ignore   | Ignore |  |
| Reserved            | 1010     | Ignore | Ignore   | Ignore |  |
| Reserved            | 0100     | Ignore | Ignore   | Ignore |  |
| Reserved            | 1110     | Ignore | Ignore   | Ignore |  |

**Mode Column**

The 'Mode' column contains the mnemonic names given to the modes of the endpoint. The mode of the endpoint is determined by the four-bit binaries in the 'Encoding' column as discussed in the following section. The Status IN and Status OUT represent the status IN or OUT stage of the control transfer.

**Encoding Column**

The contents of the 'Encoding' column represent the Mode Bits [3:0] of the Endpoint Mode Registers (Table 83 and Table 84). The endpoint modes determine how the SIE responds to different tokens that the host sends to the endpoints. For example, if the Mode Bits [3:0] of the Endpoint 0 Mode Register are set to '0001', which is NAK IN/OUT mode, the SIE will send an ACK handshake in response to SETUP tokens and NAK any IN or OUT tokens.

**SETUP, IN, and OUT Columns**

Depending on the mode specified in the 'Encoding' column, the 'SETUP', 'IN', and 'OUT' columns contain the SIE's responses when the endpoint receives SETUP, IN, and OUT tokens, respectively.

A 'Check' in the Out column means that upon receiving an OUT token the SIE checks to see whether the OUT is of zero length and has a Data Toggle (Data1/0) of 1. If these conditions are true, the SIE responds with an ACK. If any of the above conditions is not met, the SIE will respond with either a STALL or Ignore.

A 'TX Count' entry in the IN column means that the SIE will transmit the number of bytes specified in the Byte Count Bit [3:0] of the Endpoint Count Register (Table 82) in response to any IN token.

### Details of Mode for Differing Traffic Conditions

| Control Endpoint         |           |           |         |      |          |                   |   |   |   |                    |        |      |        |           |                    |
|--------------------------|-----------|-----------|---------|------|----------|-------------------|---|---|---|--------------------|--------|------|--------|-----------|--------------------|
| SIE                      | Bus Event |           |         |      | SIE      | EP0 Mode Register |   |   |   | EP0 Count Register |        |      | EP0    | Interrupt | Comments           |
| Mode                     | Token     | Count     | Dval    | D0/1 | Response | S                 | I | O | A | MODE               | DTOG   | DVAL | COUNT  | FIFO      |                    |
| <b>DISABLED</b>          |           |           |         |      |          |                   |   |   |   |                    |        |      |        |           |                    |
| 0000                     | x         | x         | x       | x    |          |                   |   |   |   |                    |        |      |        |           | Ignore All         |
| <b>STALL_IN_OUT</b>      |           |           |         |      |          |                   |   |   |   |                    |        |      |        |           |                    |
| 0011                     | SETUP     | >10       | x       | x    |          |                   |   |   |   |                    |        |      |        | junk      | Ignore             |
| 0011                     | SETUP     | <=10      | invalid | x    |          |                   |   |   |   |                    |        |      |        | junk      | Ignore             |
| 0011                     | SETUP     | <=10      | valid   | x    | ACK      | 1                 |   |   | 1 | 0001               | update | 1    | update | data      | Yes<br>ACK SETUP   |

LEGEND

In the R/W column,  
b = Both Read and Write  
r = Read Only  
w = Write Only  
c = Read/Clear  
? = Unknown  
d = calibration value. Should not change during normal use

## Radio Function Register Descriptions

All registers are read and writeable, except where noted. Registers may be written to or read from either individually or in sequential groups. A single-byte read or write reads or writes from the addressed register. Incrementing burst read and write is a sequence that begins with an address, and then reads or writes to/from each register in address order for as long as clocking continues. It is possible to repeatedly read (poll) a single register using a non-incrementing burst read. These registers are managed and configured over SPI by the user firmware running in the microcontroller function.

**Table 88. Register Map Summary**

| Address        | Mnemonic            | b7                      | b6         | b5               | b4           | b3           | b2           | b1           | b0        | Default <sup>(4)</sup> | Access <sup>(4)</sup> |          |

**Notes**

- b = read/write; r = read only; w = write only; '-' = not used, default value is undefined.
- SOP\_CODE\_ADR default = 0x17FF9E213690C782.
- DATA\_CODE\_ADR default = 0x02F9939702FA5CE3012BF1DB0132BE6F.
- PREAMBLE\_ADR default = 0x333302; The count value should be greater than 4 for DDR and greater than 8 for SDR.
- Registers must be configured or accessed only when the radio is in IDLE or SLEEP mode. The PMU, GPIOs, RSSI registers can be accessed in Active Tx and Rx mode.
- EOP\_CTRL\_ADR[6:4] should never have the value of "000" i.e. EOP Hint Symbol count should never be "0".
- PFET Bit: Setting this bit to "1" disables the FET, therefore safely allowing Vbat to be connected to a separate reference from Vcc when the PMU is disabled to the radio. om Vcc when the PMU is disabled to the radio.

## Absolute Maximum Ratings

Storage Temperature ..... -40°C to +90°C  
 Ambient Temperature with Power Applied..... 0°C to +70°C  
 Supply Voltage on any power supply pin relative to V<sub>SS</sub> ..... -0.3V to +3.9V  
 DC Voltage to Logic Inputs<sup>[11]</sup>..... -0.3V to V<sub>IO</sub> +0.3V  
 DC Voltage applied to Outputs in High-Z State..... -0.3V to V<sub>IO</sub> +0.3V

Static Discharge Voltage (Digital)<sup>[12]</sup> ..... >2000V  
 Static Discharge Voltage (RF)<sup>[12]</sup> ..... 1100V  
 Latch-up Current..... +200 mA, -200 mA  
 Ground Voltage..... 0V  
 F<sub>OSC</sub> (Crystal Frequency)..... 12 MHz ±30 ppm

## DC Characteristics (T = 25°C)

| Parameter  | Description  | Conditions  | Min. | Typ.  | Max. | Unit |
|--|--|---|------|-------|------|------|
| <b>Radio Function Operating Voltages</b>   |  |   |      |       |      |      |
| V <sub>BAT</sub>   | Battery Voltage  | 0–70°C  | 1.8  |       | 3.6  | V    |

| V <sub>ON</sub>  | Static Output High   | 15K ± 5% Ohm to V <sub>SS</sub>   | 2.8  |       | 3.6  | V    |
| V <sub>OFF</sub>   | Static Output Low  | R <sub>UP</sub> is enabled  |      |       | 0.3  | V    |

### Notes

- It is permissible to connect voltages above V<sub>IO</sub> to inputs through a series resistor limiting input current to 1 mA. AC timing not guaranteed.
- Human Body Model (HBM).
- Includes current drawn while starting crystal, starting synthesizer, transmitting packet (including SOP and CRC16), changing to receive mode, and receiving ACK handshake. Device is in sleep except during this transaction.

**DC Characteristics** (T = 25°C) (continued)

| Non-Harmonically Related Spurs (8.000 GHz)   |                            |       | -38   |       | dBm      |
| Non-Harmonically Related Spurs (1.6 GHz)   |                            |       | -34   |       | dBm      |

**Notes**

15. Except for pins P1.0, P1.1 in GPIO mode.

16. Exceptions F/3 &amp; 5C/3.

17. When using an external switching regulator to power the radio, the switching frequency should be set very far from the IF frequency of 1 MHz.

Table 89. Radio Parameters (continued)

| Parameter Description                                  | Conditions   | Min. | Typ. | Max. | Unit  |

| Package                   | Ordering Part Number |
|---------------------------|----------------------|
| 40-pin Pb-Free QFN 6x6 mm | CYRF69213-40 LFXC    |

Package Diagram

Figure 31. 40-pin Pb-Free QFN 6x6 mm

NOTES:

1.  HATCH IS SOLDERABLE EXPOSED AREA
2. REFERENCE JEDEC#: MO-220
3. PACKAGE WEIGHT: 0.086g
4. ALL DIMENSIONS ARE IN MM [MIN/MAX]

51-85190-\*A
