

## PRELIMINARY MILITARY PRODUCT SPECIFICATION

## Z16C30

### CMOS USC UNIVERSAL SERIAL CONTROLLER

#### FEATURES

- Two independent, 0 to 10Mbit/sec, full duplex channels, each with two baud rate generators and Digital Phase-Locked Loop for clock recovery.
- 32 byte data FIFO's for each receiver and transmitter.
- 12.5 MByte/sec (16 bit) data bus bandwidth.
- Multi-protocol operation under program control with independent mode selection for receiver and transmitter.
- Async mode with one to eight bits/character, 1/16 to 2 stop bits/character in 1/16 bit increments; programmable clock factor; break detect and generation; odd, even, mark, space or no parity and framing error detection. Supports one Address/Data bit and MIL STD 1553B protocols.
- Byte oriented synchronous mode with one to eight bits/character; programmable idle line condition; optional receive sync stripping; optional preamble transmission; 16- or 32-bit CRC and transmit-to-receive slaving (for X.21).
- Bisync mode with 2- to 16-bit programmable sync characters; programmable idle line condition; optional receive sync stripping; optional preamble transmission; 16- or 32-bit CRC.
- Transparent Bisync mode with EBCDIC or ASCII character code; automatic CRC handling; programmable idle line condition; optional preamble transmission; automatic recognition of DLE, SYN, SOH, ITX, ETX, ETB, EOT, ENQ and ITB.
- External character sync mode for receive.
- HDLC/SDLC mode with eight bit address compare; extended address field option; 16- or 32-bit CRC; programmable idle line condition; optional preamble transmission and loop mode.
- DMA interface with separate request and acknowledge for each receiver and transmitter.
- Channel load command for DMA controlled initialization.
- Flexible bus interface for direct connection to most microprocessors; user programmable for 8- or 16-bits wide. Directly supports 680X0 family or 8X86 family bus interfaces.
- Low power CMOS.
- Improved Radiation Tolerance
- 68 pin PGA Package.

#### GENERAL DESCRIPTION

The USC Universal Serial Controller is a dual-channel multi-protocol data communications peripheral designed for use with any conventional multiplexed or non-multiplexed bus. The USC functions as a serial-to-parallel, parallel-to-serial converter/controller and may be software configured to satisfy a wide variety of serial communications applications. The device contains a variety of new, sophisticated internal functions including two baud rate generators per channel, a digital phase-locked loop per channel, character counters for both receive and transmit in each channel and 32 byte data FIFO's for each receiver and transmitter.

The USC handles asynchronous formats, synchronous byte-oriented formats such as BISYNC and synchronous bit-oriented formats such as HDLC. This device supports virtually any serial data transfer application.

The device can generate and check CRC in any synchronous mode and can be programmed to check data integrity in various modes. The USC also has facilities for modem controls in both channels. In applications where these controls are not needed, the modem controls may be used for general-purpose I/O. The same is true for most of the other pins in each channel.

**GENERAL DESCRIPTION (Continued)**

Interrupts are supported with a daisy-chain hierarchy, with the two channels having completely separate interrupt structures.

High-speed data transfers via DMA are supported by a Request/Acknowledge signal pair for each receiver and transmitter. The device supports automatic status transfer via DMA and also allows device initialization under DMA control.

To aid the designer in efficiently programming the USC, additional literature is available. The Technical Manual describes in detail all features presented in this Product Specification and gives programming sequence hints. The Programmer's Assistant is a MS-DOS disk based programming initialization tool to be used in conjunction with the Technical Manual. There are also available assorted application notes and development boards to assist the designer in the hardware/software development.

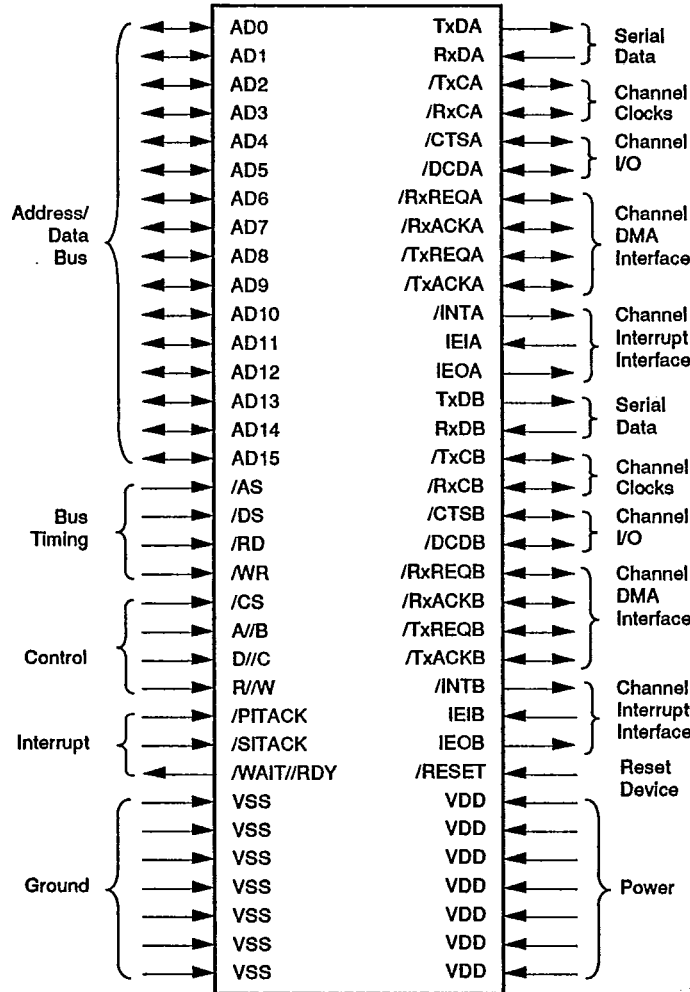

Figure 2. Pin Functions

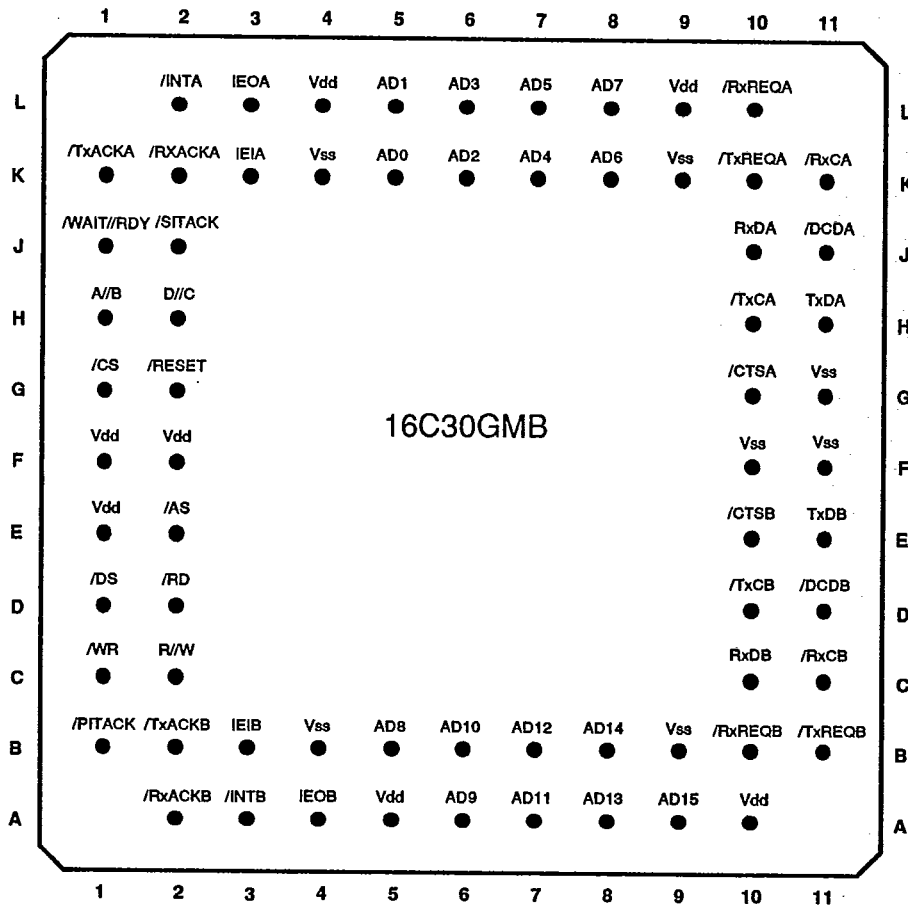

Figure 3. Pin Assignments

**PIN DESCRIPTION**

The device contains 13 pins per channel for channel I/O, 16 pins for address and data, 12 pins for CPU handshake and 14 pins for power and ground.

Three separate bus interface types are available for the device. The Bus Configuration Register (BCR) and external connections to the AD bus control selection of the bus type.

A 16-bit bus is selected by setting the BCR bit 2 to a 1.

The 8-bit bus is selected by setting BCR bit 2 to 0 and tying AD15 - AD8 to Vss.

The 8-bit bus with separate address, is selected by setting BCR bit 2 to 0. During the BCR write, AD15 is forced to a 1 and forcing AD14-AD8 to zero.

The multiplexed bus is selected for the USC if there is an Address Strobe prior to or during the transaction which writes the BCR.

If no Address Strobe is present prior to or during the transaction which writes the BCR, a non-multiplexed bus is selected (See Figure 6).

The section below describes in detail the USC pin assignment.

**/RESET.** *Reset* (input, active Low). This signal resets the device to a known state. The first write to the USC after a reset accesses the BCR to select additional bus options for the device.

**/AS.** *Address Strobe* (input, active Low). This signal is used in the multiplexed bus modes to latch the address on the AD lines. The AS signal is not used in the non-multiplexed bus modes and should be tied to  $V_{DD}$  in these cases.

**/DS.** *Data Strobe* (input, active Low). This signal strobes data out of the device during a read and may strobe an interrupt vector out of the device during an interrupt acknowledge cycle. DS also strobes data into the device during the active state of R/W.

**/RD.** *Read Strobe* (input, active Low). This signal strobes data out of the device during a read and may strobe an interrupt vector out of the device during an interrupt acknowledge cycle.

**/WR.** *Write Strobe* (input, active Low). This signal strobes data into the device during a write.

**R/W.** *Read/Write* (input). This signal determines the direction of data transfer for a read or write cycle in conjunction with DS.

**/CS.** *Chip Select* (input, active Low). This signal selects the device for access and must be asserted for read and write cycles, but is ignored during interrupt acknowledge and fly-by DMA transfers. In the case of a multiplexed bus interface, CS is latched by the rising edge of AS.

**A/B.** *Channel A/Channel B Select* (input). This signal selects between the two channels in the device. High selects channel A and Low selects channel B.

This signal is sampled and the result is latched during the BCR (Bus Configuration Register) write. It programs the sense of the *WAIT//RDY* signal appropriate for different bus interfaces. See *WAIT//RDY* below.

**D//C.** *Data/Control Select* (input). This signal, when High, provides for direct access to the RDR and TDR. In the case of a multiplexed bus interface, D//C High overrides the address provided to the device.

**/STACK.** *Status Interrupt Acknowledge* (input, active Low). This signal is a status signal that indicates that an interrupt acknowledge cycle is in progress. The device is capable

of returning an interrupt vector that may be encoded with the type of interrupt pending during this acknowledge cycle. This signal is compatible with 680x0 family microprocessors.

**/PITACK.** *Pulsed Interrupt Acknowledge* (input, active Low). This is a strobe signal that indicates that an interrupt acknowledge cycle is in progress. The device is capable of returning an interrupt vector that may be encoded with the type of interrupt pending during this acknowledge cycle.

PITACK may be programmed to accept a single pulse or double pulse acknowledge type. This programming is done in the BCR. With the double pulse type selected, the first PITACK is recognized but no action takes place. The interrupt vector is returned on the second pulse if the no vector option is not selected. The double pulse type is compatible with 8x86 family microprocessors.

**WAIT//RDY.** *Wait Data Ready* (output, active Low). This signal indicates when the data is available during a read cycle, when the device is ready to receive data during a write cycle, and when a valid vector is available during an interrupt acknowledge cycle. It may be programmed to function either as a Wait signal or a Ready signal using the state of the A/B pin during the BCR write. When A/B is High during the BCR write, this signal functions as a wait output and thus supports the *READY* function of 8X86 family microprocessors. When A/B is Low during the BCR write, this signal functions as a ready output and thus supports the *DTACK* function of 680X0 family microprocessors.

**AD15-AD0.** *Address/Data Bus* (bidirectional, active High, 3-state). The AD signals carry addresses to, and data to and from, the device. When the 16-bit non-multiplexed bus is selected, AD15-0 carry data to and from the device. Addresses are provided using a pointer within the device that is loaded with the desired register address. When the 8-bit non-multiplexed bus is selected without separate address, only AD7-0 are used to transfer data. The pointer is used for addressing; AD15-8 are unused.

When the 8-bit non-multiplexed bus is selected with separate address, AD7-0 are used to transfer data, while AD15-8 are used as an address bus. When the 16-bit multiplexed bus is selected, addresses are latched from AD7-0 and data transfers are sixteen bits wide. When the 8-bit multiplexed bus is selected without separate address, only AD7-0 are used to transfer addresses and data; AD15-8 are unused. When the 8-bit multiplexed bus with separate address is selected, only AD7-0 are used to transfer data, while AD15-8 are used as an address bus.

**/INTA, /INTB. Interrupt Request** (outputs, active Low). These signals indicate that the channel has an interrupt condition pending and is requesting service. These outputs are NOT open-drain.

**IEIA, IEIB. Interrupt Enable In** (Inputs, active High). The IEI signal for each channel is used with the accompanying IEO signal to form an interrupt daisy chain. An active IEI indicates that no device having higher priority is requesting or servicing an interrupt.

**IEOA, IEOB. Interrupt Enable Out** (outputs, active High). The IEO signal for each channel is used with the accompanying IEI signal to form an interrupt daisy chain. IEO is Low if IEI is Low, an interrupt is under service in the channel, or an interrupt is pending during an interrupt acknowledge cycle.

**/TxACKA, /TxACKB. Transmit Acknowledge** (inputs or outputs, active Low). The primary function of these signals is to perform fly-by DMA transfers to the transmit FIFOs. Also, they can be used as bit inputs or outputs.

**/RxACKA, /RxACKB. Receive Acknowledge** (inputs or outputs, active Low). The primary function of these signals is to perform fly-by DMA transfers from the receive FIFOs. Also, they can be used as bit inputs or outputs.

**TxDA, TxDB. Transmit Data** (outputs, active High, 3-state). These signals carry the serial transmit data for each channel.

**RxDA, RxDB. Receive Data** (Inputs, active High). These signals carry the serial receive data for each channel.

**/TxCA, /TxCB. Transmit Clock** (inputs or outputs, active Low). These signals are used as clock inputs for any of the functional blocks within the device. They may also be used as outputs for various transmitter signals or internal clock signals.

**/RxCA, /RxCB. Receive Clock** (inputs or outputs, active Low). These signals are used as clock inputs for any of the functional blocks within the device. They may also be used as outputs for various receiver signals or internal clock signals.

**/TxREQA, /TxREQB. Transmit Request** (inputs or outputs, active Low). The primary function of these signals is to request DMA transfers to the transmit FIFOs. They may also be used as simple inputs or outputs.

**/RxREQA, /RxREQB. Receive Request** (inputs or outputs, active low). The primary function of these signals is to request DMA transfers from the receive FIFOs. They may also be used as simple inputs or outputs.

**/CTSA, /CTSB. Clear To Send** (inputs or outputs, active Low). These signals are used as enables for the respective transmitters. They may also be programmed to generate interrupts on either transition or used as simple inputs or outputs.

**/DCDA, /DCDB. Data Carrier Detect** (Inputs or outputs, active Low). These signals are used as enables for the respective receivers. Also, they may be programmed to generate interrupts on either transition or used as simple inputs or outputs.

## ARCHITECTURE

The USC internal structure includes two completely independent full-duplex serial channels, each with two baud rate generators, a digital phase-locked loop for clock recovery, transmit and receive character counters and a full-duplex DMA interface. The two serial channels share a common bus interface. The bus interface is designed to

provide easy interface to most microprocessors, whether they employ a multiplexed, non-multiplexed, 8-bit or 16-bit bus structure. Each channel is controlled by a set of thirty 16-bit registers, nearly all of which are readable and writable. There is one additional 16-bit register in the bus interface used to configure the nature of the bus interface. The BCR functions are shown in Figure 4.

Figure 4. Bus Configuration Register

**DATA PATH**

Both the transmitter and the receiver in the channel are actually microcoded serial processors. As the data shifts through the transmit or receive shift register, the microcode watches for specific bit patterns, counts bits, and at

the appropriate time transfers data to or from the FIFOs. The microcode also checks status and generates status interrupts as appropriate.

**FUNCTIONAL DESCRIPTION**

The functional capabilities of the USC are described from two different points of view: as a data communications device, it transmits and receives data in a wide variety of data communications protocols; as a microprocessor peripheral, the USC offers such features as read/write registers, a flexible bus interface, DMA interface support and vectored interrupts.

**Data Communications Capabilities**

The USC provides two independent full-duplex channels programmable for use in any common data communication protocol. The receiver and transmitter modes are completely independent, as are the two channels. Each receiver and transmitter is supported by a 32-byte deep FIFO and a 16-bit message length counter. All modes allow optional even, odd, mark or space parity. Synchronous modes allow the choice of two 16-bit or one 32-bit CRC polynomial.

Selection of from one to eight bits-per-character is available in both receiver and transmitter, independently. Error and status conditions are carried with the data in the receive and transmit FIFOs to greatly reduce the CPU overhead required to send or receive a message. Specific, appropriately timed interrupts are available to signal such conditions as overrun, parity error, framing error, end-of-

frame, idle line received, sync acquired, transmit under-run, CRC sent, closing sync/flag sent, abort sent, idle line sent and preamble sent. In addition, several useful internal signals such as receive FIFO load, received sync, transmit FIFO read and transmission complete may be sent to pins for use by external circuitry.

**Asynchronous Mode.** The receiver and transmitter can handle data at a rate of 1/16, 1/32, or 1/64 the clock rate. The receiver rejects start bits less than one-half a bit time and will not erroneously assemble characters following a framing error. The transmitter is capable of sending one, two, or anywhere in the range of 1/16th to two stop bits per character in 1/16 bit increments.

**External Sync Mode.** The receiver is synchronized to the receive data stream by an externally-supplied signal on a pin for custom protocol applications.

**Isochronous Mode.** Both transmitter and receiver may operate on start-stop (async) data using a 1x clock. The transmitter can send one or two stop bits.

**Asynchronous With Code Violations.** This is similar to Isochronous mode except that the start bit is replaced by a three bit-time code violation pattern as in MIL-STD 1553B. The transmitter can send zero, one or two stop bits.

**FUNCTIONAL DESCRIPTION (Continued)**

**Asynchronous With Code Violations.** This is similar to isochronous mode except that the start bit is replaced by a three bit-time code violation pattern as in MIL-STD 1553B. The transmitter can send zero, one or two stop bits.

**Monosync Mode.** In this mode, a single character is used for synchronization. The character can either be eight bits long with an arbitrary data character length, or the sync character length may be programmed to match the data character length. The receiver is capable of automatically stripping sync characters from the received data stream. The transmitter may be programmed to automatically send CRC on either an overrun or at the end of a programmed message length.

**Bisync Mode.** This mode is identical to monosync mode except that character synchronization requires two successive characters for synchronization. The two characters need not be identical.

**HDLC Mode.** In this mode, the receiver recognizes flags, performs optional address matching, accommodates extended address fields, 8- or 16-bit control fields and logical control fields, performs zero deletion and CRC checking. The receiver is capable of receiving shared-zero flags, recognizes the abort sequence and can receive arbitrary length messages. The transmitter automatically sends opening and closing flags, performs zero insertion and can be programmed to send an abort, an extended abort, a flag or CRC and a flag on transmit overrun. Also, the transmitter automatically sends the closing flag with optional CRC at the end of a programmed message length. Shared-zero flags are selected in the transmitter and a separate character length may be programmed for the last character in the frame.

**Bisync Transparent Mode.** In this mode, the synchronization pattern is DLE-SYN, programmable selected from either ASCII or EBCDIC encoding. The receiver recognizes control character sequences and automatically handles CRC calculations without CPU intervention. The transmitter can be programmed to send either SYN, DLE-SYN, CRC-SYN, or CRC-DLE-SYN upon overrun and can automatically send the closing DLE-SYN with optional CRC at the end of a programmed message length.

**NBIP Mode.** This mode is identical to async except that the receiver checks for the status of an additional address/data bit between the parity bit and the stop bit. The value of this bit is FIFO'ed along with the data. This bit is automatically inserted in the transmitter with the value that is FIFO'ed with the transmit data.

**802.3 Mode.** This mode implements the data format of IEEE 802.3 with 16-bit address compare. In this mode, DCD and CTS are used to implement the carrier sense and collision detect interactions with the receiver and transmitter.

**Slaved Monosync Mode.** This mode is available only in the transmitter and allows the transmitter (operating as though it were in monosync mode) to send data that is byte-synchronous to the data being received by the receiver.

**HDLC Loop Mode.** This mode is also available only in the transmitter and allows the USC to be used in an HDLC loop configuration. In this mode, the receiver is programmed to operate in HDLC mode so that the transmitter echos received messages. Upon receipt of a particular bit pattern (actually a sequence of seven consecutive ones) the transmitter breaks the loop and inserts its own frame(s).

**Data Encoding**

The USC may be programmed to encode and decode the serial data in any of eight different ways as shown in Figure 5. The transmitter encoding method is selected independently of the receiver decoding method.

**NRZ.** In NRZ, 1 is represented by a high level for the duration of the bit cell and a 0 is represented by a Low level for the duration of the bit cell.

**NRZB.** Data is inverted from NRZ.

**NRZI-Mark.** In NRZI-Mark, 1 is represented by a transition at the beginning of the bit cell. That is, the level present in the preceding bit cell is reversed. A 0 is represented by the absence of a transition at the beginning of the bit cell.

**NRZI-Space.** In NRZI-Space, 1 is represented by the absence of a transition at the beginning of the bit cell. That is, the level present in the preceding bit cell is maintained. A 0 is represented by a transition at the beginning of the bit cell.

**Biphase-Mark.** In Biphase-Mark, 1 is represented by a transition at the beginning of the bit cell and another transition at the center of the bit cell. A 0 is represented by a transition at the beginning of the bit cell only.

**Biphase-Space.** In Biphase-Space, 1 is represented by a transition at the beginning of the bit cell only. A 0 is represented by a transition at the beginning of the bit cell and another transition at the center of the bit cell.

Figure 5. Data Encoding

**Biphase-Level.** In Biphase-Level, 1 is represented by a High during the first half of the bit cell and a Low during the second half of the bit cell. A 0 is represented by a Low during the first half of the bit cell and a High during the second half of the bit cell.

**Differential Biphase-level.** In Differential Biphase-Level, 1 is represented by a transition at the center of the bit cell, with the opposite polarity from the transition at the center of the preceding bit cell. A 0 is represented by a transition at the center of the bit cell with the same polarity as the transition at the center of the preceding bit cell. In both cases there may be transitions at the beginning of the bit cell to set up the level required to make the correct center transition.

**Character Counters**

Each channel in the USC contains a 16-bit character counter for both receiver and transmitter. The receive character counter may be preset either under software control or automatically at the beginning of a receive message. The counter decrements with each receive character and at the end of the receive message the current value in the counter is automatically loaded into a four-deep FIFO. This allows DMA transfer of data to proceed without CPU intervention at the end of a received message, as the values in the FIFO allow the CPU to determine message boundaries in memory. Similarly, the transmit character counter is loaded either under software

control or automatically at the beginning of a transmit message. The counter is decremented with each write to the transmit FIFO. When the counter has decremented to zero, and that byte is sent, the transmitter automatically terminates the message in the appropriate fashion (usually CRC and the closing flag or sync character) without requiring CPU intervention.

**Baud Rate Generators**

Each channel in the USC contains two baud generators. Each generator consists of a 16-bit time constant register and a 16-bit down counter. In operation, the counter decrements with each baud rate generator clock, with the time constant automatically reloaded when the count reaches zero. The output of the baud rate generator toggles when the counter reaches a count of one-half of the time constant and again when the counter reaches zero. A new time constant may be written at any time but the new value will not take effect until the next load of the counter. The outputs of both baud rate generators are sent to the clock multiplexer for use internally or externally. The baud rate generator output frequency is related to the baud rate generator input clock frequency by the following formula:

$$\text{Output frequency} = \frac{\text{Input frequency}}{(\text{time constant} + 1)}$$

This allows an output frequency in the range of 1 to 1/65536 of the input frequency, inclusive.

**FUNCTIONAL DESCRIPTION (Continued)****Digital Phase-Locked Loop**

Each channel in the USC contains a Digital Phase-Locked Loop (DPLL) to recover clock information from a data stream with NRZI or Biphase encoding. The DPLL is driven by a clock that is nominally 8, 16 or 32 times the receive data rate. The DPLL uses this clock, along the data stream, to construct a clock for the data. This clock may then be routed to the receiver, transmitter, or both, or to a pin for use externally. In all modes the DPLL counts the input clock to create nominal bit times. As the clock is counted, the DPLL watches the incoming data stream for transitions. Whenever a transition is detected, the DPLL makes a count adjustment (during the next counting cycle), to produce an output clock which tracks the incoming bit cells. The DPLL provides properly phased transmit and receive clocks to the clock multiplexer.

**Counters**

Each channel contains two 5-bit counters, which are programmed to divide an input clock by 4, 8, 16 or 32. The inputs of these two counters are sent to the clock multiplexer. The counters are used as prescalers for the baud rate generators, or to provide a stable transmit clock from a common source when the DPLL is providing the receive clock.

**Clock Multiplexer**

The clock multiplexer in each channel selects the clock source for the various blocks in the channel and selects an internal clock signal to potentially be sent to either the RxC or TxC pin.

**Test Modes**

The USC is programmed for local loopback or auto echo operation. In local loopback, the output of the transmitter is internally routed to the input of the receiver. This allows testing of the USC data paths without any external logic. Auto echo connects the RxD pin directly to the TxD pin. This is useful for testing serial links external to the USC.

**I/O Interface Capabilities**

The USC offers the choice of polling, interrupt (vectored or non-vectored) and block transfer modes to transfer data, status and control information to and from the CPU.

**Polling.** All interrupts are disabled. The registers in the USC are automatically updated to reflect current status. The CPU polls the Daisy Chain Control Register (DCCR) to determine status changes and then reads the appropriate status register to find and respond to the change in status. USC status bits are grouped according to function to simplify this software action.

**Interrupt.** When a USC responds to an interrupt acknowledge from the CPU, an interrupt vector may be placed on the data bus. This vector is held in the Interrupt Vector Register (IVR). To speed interrupt response time, the USC modifies three bits in this vector to indicate which type of interrupt is being requested.

Each of the six sources of interrupts in each channel of the USC (Receive Status, Receive Data, Transmit Status, Transmit Data, I/O Status and Device Status) has three bits associated with the interrupt source: Interrupt Pending (IP), Interrupt-Under-Service (IUS) and Interrupt Enable (IE). If the IE bit for a given source is set, that source can request interrupts. Note that individual sources within the six groups also have interrupt enable bits which are set for the particular source. In addition, there is a Master Interrupt Enable (MIE) bit in each channel which globally enables or disables interrupts within the channel.

The other two bits are related to the interrupt priority chain. A channel in the USC may request an interrupt only when no higher priority interrupt source is requesting one, e.g., when IEI is High for the channel. In this case, the channel activates the INT signal. The CPU then responds with an interrupt acknowledge cycle, and the interrupting channel places a vector on the data bus.

In the USC, the IP bit signals that an interrupt request is being serviced. If an IUS is set, all interrupt sources of lower priority within the channel and external to the channel are prevented from requesting interrupts. The internal interrupt sources are inhibited by the state of the internal daisy chain, while lower priority devices are inhibited by the IEO output of the channel being pulled Low and propagated to subsequent peripherals. An IUS bit is set during an interrupt acknowledge cycle if there are no higher priority devices requesting interrupts.

There are six sources of interrupt in each channel: Receive Status, Receive Data, Transmit Status, Transmit Data, I/O Status and Device Status, prioritized in that order within the channel. There are six sources of Receive Status interrupt, each individually enabled: exited hunt, idle line, break/abort, code violation/end-of-transmission/end-of-frame, parity error and overrun error. The Receive Data interrupt is generated whenever the receive FIFO fills with data beyond the level programmed in the Receive Interrupt Control Register (RICR).

There are six sources of Transmit Status interrupt, each individually enabled: preamble sent, idle line sent, abort sent, end-of-frame/end-of-transmission sent, CRC sent and underrun error. The Transmit Data interrupt is generated whenever the transmit FIFO empties below the level programmed in the Transmit Interrupt Control Register (TICR). The I/O Status interrupt serves to report transitions on any of six pins. Interrupts are generated on either or both edges with separate selection and enables for each pin. The pins programmed to generate I/O Status interrupts are /RxC, /TxC, /RxREQ, /TxREQ, /DCD and /CTS. These interrupts are independent of the programmed function of the pins. The Device Status interrupt has four separately enabled sources: receive character count FIFO overflow, DPLL sync acquired, BRG1 zero count and BRGO zero count.

**Block Transfer Mode.** The USC accommodates block transfers via DMA through the /RxREQ, /TxREQ, /RxACK and /TxACK pins. The /RxREQ signal is activated when the fill level of the receive FIFO exceeds the value programmed in the RICR. The DMA may respond with either a normal bus transaction or by activating the /RxACK pin to read the data directly (fly-by transfer). The /TxREQ signal is activated when the empty level of the transmit FIFO falls below the value programmed in the TICR. The DMA may respond either with a normal bus transaction or by activating the /TxACK pin to write the data directly (fly-by transfer). The /RxACK and /TxACK pin functions for this mode are controlled by the Hardware Configuration Register (HCR). Then using the /RxACK and /TxACK pins to transfer data, no chip select is necessary; these are dedicated strobes for the appropriate FIFO.

## PROGRAMMING

The Programmers Assistant (MS DOS based) and Technical Manual are available to provide details about programming the USC. Also included are explanations and features of all registers in the USC.

The registers in each USC channel are programmed by the system to configure the channels. Before this can occur, however, the system must program the bus interface by writing to the Bus Configuration Register (BCR). The BCR has no specific address and is only accessible immediately after a hardware reset of the device. The first write to the USC, after a hardware reset, programs the BCR. From that time on the normal channel registers may be accessed. No specific address need be presented to the USC for the BCR write; the USC knows that the first write after a hardware reset is destined for the BCR.

In the multiplexed bus case, all registers are directly addressable via the address latched by /AS at the beginning of a bus transaction. The address is decoded from either AD6-AD0 or AD7-AD1. This is controlled by the Shift Right/Shift Left bit in the BCR. The address maps for these two cases are shown in Table 1. The D//C pin is still used to directly access the receive and transmit data registers (RDR and TDR) in the multiplexed bus; if D//C is High the address latched by /AS is ignored and an access of RDR or TDR is performed.

In the non-multiplexed bus case, the registers in each channel are accessed indirectly using the address pointer in the Channel Command/Address Register (CCAR) in each channel. The address of the desired register is first

written to the CCAR and then the selected register is accessed; the pointer in the CCAR is automatically cleared after this access. The RDR and TDR are accessed directly using the D//C pin, without disturbing the contents of the pointer in the CCAR.

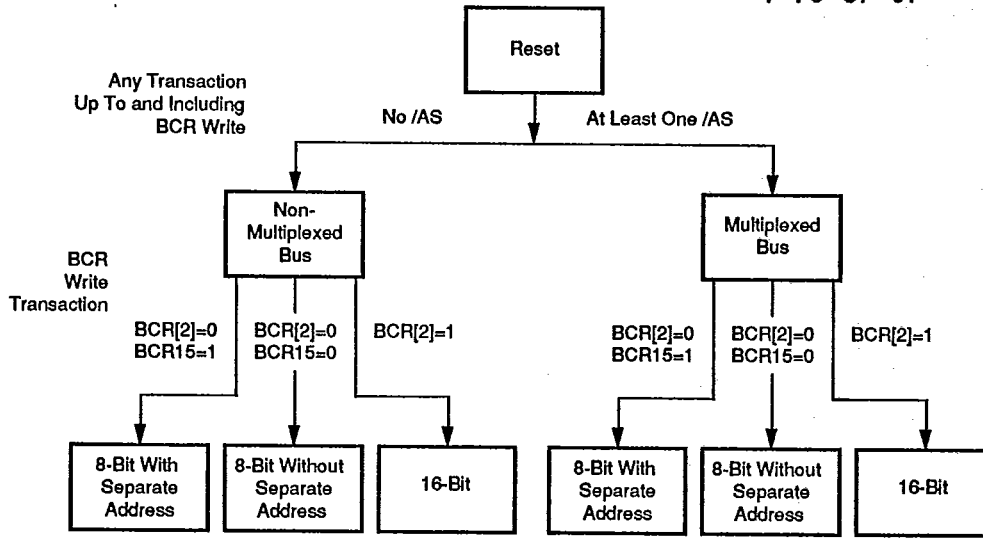

**Table 1. Multiplexed Bus Address Assignments**

Address Signal	Shift Left	Shift Right
Byte/Word *Access	AD7	AD6
Address 4	AD6	AD5
Address 3	AD5	AD4
Address 2	AD4	AD3
Address 1	AD3	AD2
Address 0	AD2	AD1
Upper/Lower *Byte Select	AD1	AD0

There are two important things to note about the USC. First, the Channel Reset bit in the CCAR places the channel in the reset state. To exit this reset state either a word of all zeros must be written to the CCAR (16-bit bus) or a byte of all zeros must be written to the lower byte of the CCAR (8-bit bus). The second thing to note is that after reset, the transmit and receive clocks are not connected. The first thing that should be done in any initialization sequence is a write to the Clock Mode Control Register (CMCR) to select a clock source for the receiver and transmitter.

The register addressing is shown in Table 2, and the bit assignments for the registers are shown in Figure 6.

T-75-37-07

Note:  
The presence of one transaction with an AS active, between reset up to and including the BCR write, chooses a multiplexed type of bus.

**USC TIMING**

The USC interface timing is similar to that found on a static RAM, except that it is much more flexible. Up to eight separate timing strobe signals may be present on the interface: /DS, /RD, /WR, /PITACK, /RxACKA, /RxACKB, /TxACKA and /TxACKB. Only one of these timing strobes may be active at any time. Should the external logic activate more than one of these strobes at the same time the USC will enter a pre-reset state that is only exited by a hardware reset. Do not allow overlap of timing strobes. The timing diagrams, beginning on the next page, illustrate the different bus transactions possible, with the necessary setup, hold and delay times.

**ABSOLUTE MAXIMUM RATINGS**

Voltages on all pins with respect to V<sub>SS</sub> ..... -0.3 V to +7.0 V  
 Voltages on all inputs with respect to V<sub>SS</sub> ..... -0.3V to V<sub>CC</sub> +0.3V  
 Operating Ambient Temperature ..... See Ordering Information  
 Storage Temperature ..... -65°C to +150°C

Stresses greater than those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; operation of the device at any condition above those indicated in the operational sections of these specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

**STANDARD TEST CONDITIONS**

The DC Characteristics and Capacitance section below apply for the following standard test conditions, unless otherwise noted. All voltages are referenced to GND. Positive current flows into the referenced pin. Standard conditions are as follows:

- +4.5 V < V<sub>CC</sub> < +5.5 V
- GND = 0 V
- T<sub>A</sub> as specified in Ordering Information

Figure 54. Standard Test Load

**CAPACITANCE**

Symbol	Parameter	Min	Max	Unit	Condition
C <sub>IN</sub>	Input Capacitance		10	pf	Unmeasured Pins Returned to Ground
C <sub>OUT</sub>	Output Capacitance		15	pf	
C <sub>I/O</sub>	Bidirectional Capacitance		20	pf	

f = 1MHz, over specified temperature range.  
 Unmeasured pins returned to ground.

**MISCELLANEOUS** Transistor Count - 174,000

**Notes:**

- [1] Direct address is any of A/B, D/C or AD15-AD8 used as an address bus.  
 [2] The parameter applies only when /AS is not present.  
 [3] Strobe is any of /DS, /RD, /WR, /PITACK, /RxACK or /TxACK.  
 [4] Parameter applies only if read empties the receive FIFO.  
 [5] Parameter applies only if write fills the transmit FIFO.

4	ThRxD(RxCf)	RxD to /RxC↓ Hold Time (x1 Mode)	40		[1,4]
5	TsSy(RxC)	/DCD as /SYNC to /RxC↑ Setup Time	0		[1]
6	ThSy(RxC)	/DCD as /SYNC to /RxC↑ Hold Time (x1 Mode)	40		[1]
7	TdTxCl(TxD)	/TxC↓ to TxD Delay		50	[2]
8	TdTxCr(TxD)	/TxC↑ to TxD Delay		50	[2,4]
9	TwRxCh	/RxC High Width	40		
10	TwRxCl	/RxC Low Width	40		
11	TcRxC	/RxC Cycle Time	100		
12	TwTxCh	/TxC High Width	40		
13	TwTxCl	/TxC Low Width	40		
14	TcTxC	/TxC Cycle Time	100		
15	TwExT	/DCD or /CTS Pulse Width	70		
16	TWSY	/DCD as /SYNC Input Pulse Width	70		

### AC CHARACTERISTICS

#### Z16C30 System Timing

No	Symbol	Parameter	10 MHz		Notes
			Min	Max	
1	TdRxC(REQ)	/RxC↑ to /RxREQ Valid Delay		100	[2]
2	TdRxC(RxC)	/TxC↑ to /RxC as Receiver Output Valid Delay		100	[2]
3	TdRxC(INT)	/RxC↑ to /INT Valid Delay		100	[2]
4	TdTxC(REQ)	/TxC↓ to /TxREQ Valid Delay		100	[3]
5	TdTxC(TxC)	/RxC↓ to /TxC as transmitter Output Valid Delay		100	
6	TdTxC(INT)	/TxC↓ to /INT Valid Delay		100	[3]
7	TdEXT(INT)	/CTS, /DCD, /TxREQ, /RxREQ transition to /INT Valid Delay		100	

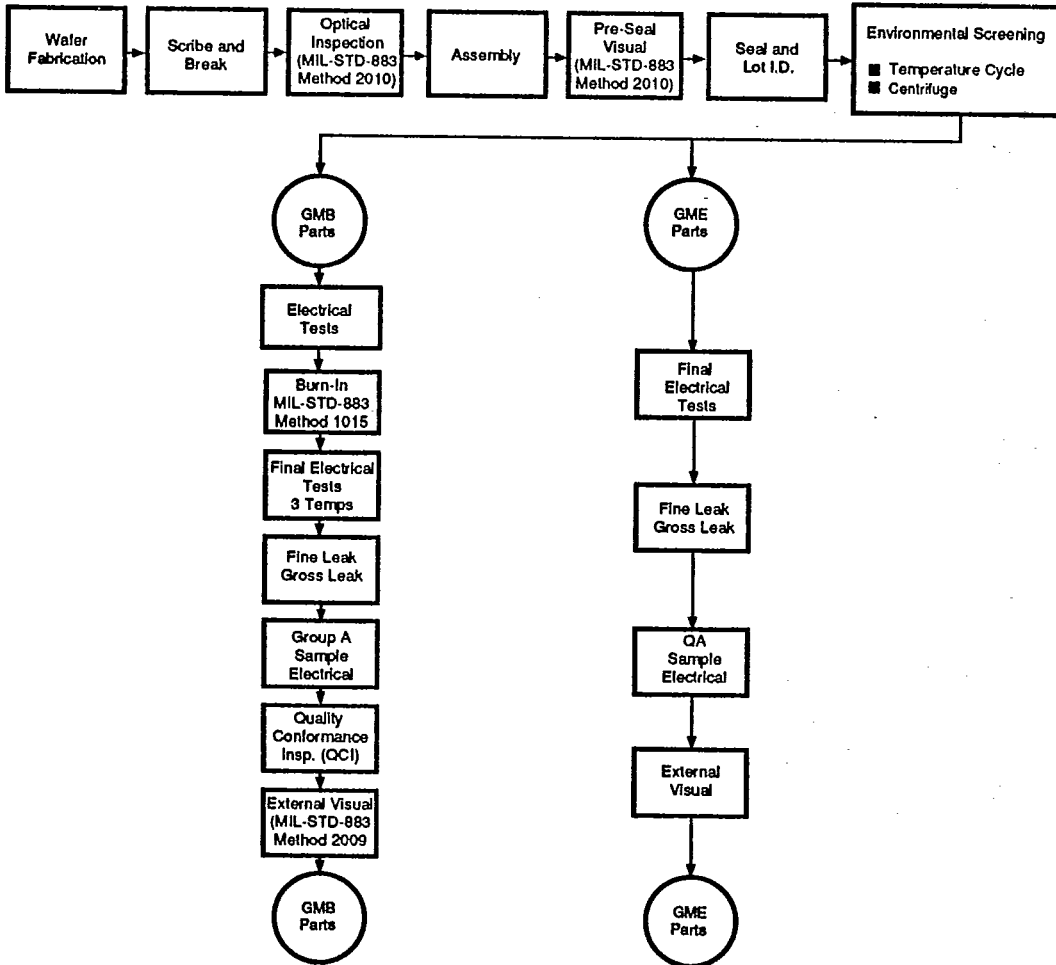

#### Notes:

- [1] /RxC is /RxC or /TxC, whichever is supplying the receive clock.  
 [2] /TxC is /TxC or /RxC, whichever is supplying the transmit clock.  
 [3] /TxC is /TxC or /RxC, whichever is supplying the transmit clock.  
 [4] Parameter applies only to FM encoding/decoding.

**MIL-STD-883 MILITARY PROCESSED PRODUCT**

- Mil-Std-883 establishes uniform methods and procedures for testing microelectronic devices to insure the electrical, mechanical, and environmental integrity and reliability that is required for military applications.
- Mil-Std-883 Class B is the industry standard product assurance level for military ground and aircraft application.
- The total reliability of a system depends upon tests that are designed to stress specific quality and reliability concerns that affect microelectronic products.
- The following tables detail the 100% screening and electrical tests, sample electrical tests, and Qualification/Quality Conformance testing required.

**Zilog Military Product Flow**

T-75-37-07

**Table I**  
**MIL-STD-883 Class B Screening Requirements**  
**Method 5004**

Test	Mil-Std-883 Method	Test Condition	Requirement
Internal Visual	2010	Condition B	100%
Temperature Cycle	1010	Condition C	100%
Constant Acceleration (Centrifuge)	2001	Condition E or D <sup>(Note 1)</sup> , Y <sub>1</sub> Axis Only	100%
Initial Electrical Tests		Zilog Military Electrical Specification Static/DC T <sub>C</sub> = +25°C	100%
Burn-In	1015	Condition D <sup>(Note 2)</sup> , 160 hours, T <sub>A</sub> = +125°C	100%
Interim Electrical Tests		Zilog Military Electrical Specification Static/DC T <sub>C</sub> = +25°C	100%
PDA Calculation		PDA = 5%	100%
Final Electrical Tests		Zilog Military Electrical Specification Static/DC T <sub>C</sub> = +125°C, -55°C Functional, Switching/AC T <sub>C</sub> = +25°C	100%
Fine Leak	1014	Condition B	100%
Gross Leak	1014	Condition C	100%
Quality Conformance Inspection (QCI)			
Group A	Each Inspection Lot	5005 (See Table II)	Sample
Group B	Every Week	5005 (See Table III)	Sample
Group C	Periodically (Note 3)	5005 (See Table IV)	Sample
Group D	Periodically (Note 3)	5005 (See Table V)	Sample
External Visual	2009		100%
QA—Ship			100%

## NOTES:

1. Applies to larger packages which have an inner seal or cavity perimeter of two inches or more in total length or have a package mass of ≥5 grams.
2. In process of fully implementing of Condition D Burn-In Circuits. Contact factory for copy of specific burn-in circuit available.
3. Performed periodically as required by Mil-Std-883, paragraph 1.2.1 b(17).

T-75-37-07

**Table II Group A**  
**Sample Electrical Tests**  
**MIL-STD-883 Method 5005**

Subgroup	Tests	Temperature (T <sub>c</sub> )	LTPD Max Accept = 2
Subgroup 1	Static/DC	+ 25°C	2
Subgroup 2	Static/DC	+ 125°C	3
Subgroup 3	Static/DC	- 55°C	5
Subgroup 7	Functional	+ 25°C	2
Subgroup 8	Functional	- 55°C and + 125°C	5
Subgroup 9	Switching/AC	+ 25°C	2
Subgroup 10	Switching/AC	+ 125°C	3
Subgroup 11	Switching/AC	- 55°C	5

## NOTES:

- The specific parameters to be included for tests in each subgroup shall be as specified in the applicable detail electrical specification. Where no parameters have been identified in a particular subgroup or test within a subgroup, no Group A testing is required for that subgroup or test.
- A single sample may be used for all subgroup testing. Where required size exceeds the lot size, 100% inspection shall be allowed.
- Group A testing by subgroup or within subgroups may be performed in any sequence unless otherwise specified.

<b>Subgroup 8</b> (Note 5) Electrostatic Discharge Sensitivity	3015	Zilog Military Electrical Specification Static/DC T <sub>C</sub> = + 25°C A = 20-2000V B = >2000V Zilog Military Electrical Specification Static/DC T <sub>C</sub> = + 25°C	15/0

## NOTES

1. Number of leads inspected selected from a minimum of 3 devices.
2. Number of bond pulls selected from a minimum of 4 devices.
3. Test applicable only if the package contains a desiccant.
4. Test not required if either 100% or sample seal test is performed between final electrical tests and external visual during Class B screening.
5. Test required for initial qualification and product redesign.

NOTES:

1. Lead Integrity Condition D for leadless chip carriers.
2. Applies to larger packages which have an inner seal or cavity perimeter of two inches or more in total length or have a package mass of ≥5 grams.
3. Not applicable to leadless chip carriers.
4. LTPD based on number of leads.
5. Not applicable for solder seal packages.

PACKAGE INFORMATION

68-Pin PGA Package

**ORDERING INFORMATION**

T-75-37-07

Z16C30 USC

10 MHz  
68-Pin PGA Package  
Z16C3010GMB  
Z16C3010GME

**CODES**

**PACKAGE**

G = PGA Package

**TEMPERATURE**

M = -55°C to +125°C

**ENVIRONMENTAL**

E = Hermetic Standard

B = 833 Class B Military Flow

Example:

Z16C3010GMB is a 16C30, 10 MHz, 68-Pin PGA, -55°C to +125°C, Processed to Class B, Mil-Std-883C
