

## Stereo 2.6W Audio Amplifier(With Gain Control)

### Features

- Low operating current with 6mA
- Improved depop circuitry to eliminate turn-on transients in outputs
- High PSRR
- Internal gain control, eliminate external components.
- 2.6W per channel output power into 3Ω load at 5V, BTL mode
- Multiple input modes allowable selected by HP/LINE pin
- Two output modes allowable with BTL and SE modes selected by SE/BTL pin
- Low current consumption in shutdown mode (50μA)
- Short Circuit Protection
- TSSOP-24-P with thermal pad package
- Lead Free Available (RoHS Compliant)

### Applications

- NoteBook PC
- LCD Monitor

### General Description

APA2035 is a monolithic integrated circuit, which provides internal gain control, and a stereo bridged audio power amplifiers capable of producing 2.6W (1.9W) into 3Ω with less than 10% (1.0%) THD+N. By control the two gain setting pins, Gain0 and Gain1, The amplifier can provide 6dB, 15.6dB, 21.6dB and 27dB gain settings. The advantage of internal gain setting can be less components and PCB area. Both of the depop circuitry and the thermal shutdown protection circuitry are integrated in APA2035, that reduces pops and clicks noise during power up or shutdown mode operation. It also improved the power off pop noise and protects the chip from being destroyed by over temperature and short current failure.

To simplify the audio system design APA2035 combines a stereo bridge-tied loads (BTL) mode for speaker drive and a stereo single-end (SE) mode for headphone drive into a single chip, where both modes are easily switched by the SE/BTL input control pin signal. Besides the multiple input selections is used for portable audio system.

## Pin Descriptions

Pin name	Pin no.	Config.	Function Description
GND	1, 12, 13, 24	-	Ground connection, Connected to thermal pad.
GAIN0	2	I/P	Input signal for internal gain setting
GAIN1	3	I/P	Input signal for internal gain setting
LOUT+	4	O/P	Left channel positive output in BTL mode and SE mode
LLINEIN	5	I/P	Left channel line input terminal, selected when HP/LINE is held low.
RLINEIN	23	I/P	Right channel line input terminal, selected when HP/LINE is held low.
LHPIN	6	O/P	Left channel headphone input terminal, selected when HP/LINE is held high.
PV <sub>DD</sub>	7, 18	-	Supply voltage only for power amplifier
RIN+	8	I/P	Right channel positive signal input, when differential signal is accepted.
LOUT-	9	O/P	Left channel negative output in BTL mode and high impedance in SE mode
LIN+	10	I/P	Left channel positive signal input, when differential signal is accepted.
BYPASS	11	-	Bypass voltage
PCBEEP	14	I/P	PC-beep signal input
SE/BTL	15	I/P	Output mode control input pin, high for SE output mode and low for BTL mode
ROUT-	16	O/P	Right channel negative output in BTL mode and high impedance in SE mode
HP/LINE	17	I/P	Multi-input selection input, headphone mode when held high, line-in mode when held low
V <sub>DD</sub>	19	-	Supply voltage for internal circuit excepting power amplifier.
RHPIN	20	I/P	Right channel headphone input terminal, selected when HP/LINE is held high.
ROUT+	21	O/P	Right channel positive output in BTL mode and SE mode
SHUTDOWN	22	I/P	It will be into shutdown mode when pull low
RLINEIN	23	I/P	Right channel line input terminal, selected when HP/LINE is held low

## Application Descriptions

### BTL Operation

The APA2035 has two pairs of operational amplifiers internally, allowed for different amplifier configurations.

Figure 1: APA2035 internal configuration (each channel)

The OP1 and OP2 are all differential drive configuration, The differential drive configuration doubling the voltage swing on the load compare to the single-ending configuration, the differential gain for each channel is

$2 \times (\text{Gain of SE mode})$ .

By driving the load differentially through outputs OUT+ and OUT-, an amplifier configuration commonly referred to as bridged mode is established. BTL mode operation is different from the classical single-ended SE amplifier configuration where one side of its load is connected to ground.

A BTL amplifier design has a few distinct advantages over the SE configuration, as it provides differential drive to the load, thus doubling the output swing for a specified supply voltage. Four times the output power is possible as compared to a SE amplifier under the same conditions. A BTL configuration, such as the one used in APA2035, also creates a second advantage over SE amplifiers. Since the differential outputs, ROUT+, ROUT-, LOU+, and LOU-, are biased at half-supply, no need DC voltage exists across the load.

## Application Descriptions (Cont.)

### BTL Operation (Cont.)

This eliminates the need for an output coupling capacitor which is required in a single supply, SE configuration.

### Single-Ended Operation

Consider the single-supply SE configuration shown Application Circuit. A coupling capacitor is required to block the DC offset voltage from reaching the load. These capacitors can be quite large (approximately 33μF to 1000μF) so they tend to be expensive, occupy valuable PCB area, and have the additional drawback of limiting low-frequency performance of the system (refer to the Output Coupling Capacitor).

The rules described should be following relationship:

$$\frac{1}{C_{bypass} \times 160k\Omega} \leq \frac{1}{R_i C_i} \ll \frac{1}{R_L C_C} \quad (1)$$

### Output SE/BTL Operation

The ability of the APA2035 to easily switch between BTL and SE modes is one of its most important cost saving features. This feature eliminates the requirement for an additional headphone amplifier in applications where internal stereo speakers are driven in BTL mode but external headphone or speakers must be accommodated.

Internal to the APA2035, two separate amplifiers drive OUT+ and OUT- (see Figure 1). The SE/BTL input controls the operation of the follower amplifier that drives LOUT- and ROUT-.

- When SE/BTL is held low, the OP2 is activated and the APA2035 is in the BTL mode.
- When SE/BTL is held high, the OP2 is in a high output impedance state, which configures the APA2035 as SE driver from OUT+. I<sub>DD</sub> is reduced by approximately one-half in SE mode.

Control of the SE/BTL input can be a logic-level TTL source or a resistor divider network or the stereo headphone jack with switch pin as shown in Application Circuit.

Figure 2: SE/BTL input selection by phonejack plug

In Figure 2, input SE/BTL operates as follows:

When the phonejack plug is inserted, the 1kΩ resistor is disconnected and the SE/BTL input is pulled high and enables the SE mode. When the input goes high level, the OUT- amplifier is shutdown causing the speaker to mute. The OUT+ amplifier then drives through the output capacitor (CO) into the headphone jack.

When there is no headphone plugged into the system, the contact pin of the headphone jack is connected from the signal pin, the voltage divider set up by resistors 100kΩ and 1kΩ. Resistor 1kΩ then pulls low the SE/BTL pin, enabling the BTL function.

### Input HP/LINE Operation

APA2035 amplifier has two separate inputs for each of the left and right stereo channels. An internal multiplexer selects which input will be connected to the amplifier based on the state of the HP/LINE pin on the IC.

- To select the line inputs, set HP/LINE pin tied to low level
- To enable the headphone inputs, set HP/LINE pin tied to high level

## Application Descriptions

### Input HP/LINE Operation (Cont.)

Refer to the application circuit, the voltage divider of 100kΩ and 1kΩ sets the voltage at the HP/LINE pin to be approximately 50mV when there are no headphones plugged into the system. This logic low voltage at the HP/LINE pin enables the APA2035 and places it LINE input mode operation.

When a set of headphones is plugged into the system, the contact pin of the headphone jack is disconnected from the signal pin, interrupting the voltage divider set up by resistors 100kΩ. Resistor 100kΩ then pulls-up the HP/LINE pin, enabling the headphone input function.

### Differential Input Operation

APA2035 can accept the differential input signal, and it can improve the CMRR (Common Mode Rejection ratio). For example: when apply differential input signals to APA2035, connect positive input signals to the IN+ (LIN+ and RIN+) of APA2035 and negative input signals to the IN- (LIN- and RIN-) of APA2035.

When input signals are single-end, just connect IN+ (LIN+ and RIN+) to ground via a capacitor.

### Input Resistance, Ri

The APA2035 provides four gain settings decided by GAIN0 and GAIN1 input pins in Differential mode and it becomes 0dB fixed gain when SE mode is selected. In table 1, internal resistors Ri and Rf according to BTL operation set the gain for each audio input of the APA2035.

GAIN0	GAIN1	Ri	Rf	SE/BTL	Av
0	0	90KΩ	90KΩ	0	6dB
0	1	45KΩ	135KΩ	0	15.6dB
1	0	25.7KΩ	154.3KΩ	0	21.6dB
1	1	13.85KΩ	166.15KΩ	0	27.6dB
X	X	90KΩ	90KΩ	1	0dB

Table 1: The close loop gain setting resistance Ri/Rf

BTL mode operation brings about the factor 2 in the gain equation due to the inverting amplifier mirroring the voltage swing across the load. The input resistance has wide variation (+/-10%) caused by manufacture.

### Input Capacitor, Ci

In the typical application an input capacitor, Ci, is required to allow the amplifier to bias the input signal to the proper DC level for optimum operation. In this case, Ci and the minimum input impedance Ri form a high-pass filter with the corner frequency determined in the following equation:

$$f_c(\text{highpass}) = \frac{1}{2\pi R_{i(\text{min})} \times C_i} \quad (2)$$

The value of Ci is important to consider as it directly affects the low frequency performance of the circuit. Consider the example where Ri is 90kΩ when 6dB gain is setting and the specification calls for a flat bass response down to 40Hz. Equation is reconfigured as follows:

$$C_i = \frac{1}{2\pi R_i f_c} \quad (3)$$

Consider to input resistance variation, the Ci is 0.04μF so one would likely choose a value in the range of 0.1μF to 1.0μF.

A further consideration for this capacitor is the leakage path from the input source through the input network (Ri+Rf, Ci) to the load. This leakage current creates a DC offset voltage at the input to the amplifier that reduces useful headroom, especially in high gain applications. For this reason a low-leakage tantalum or ceramic capacitor is the best choice. When polarized capacitors are used, the positive side of the capacitor should face the amplifier input in most applications as the DC level there is held at  $V_{DD}/2$ , which is likely higher than the source DC level. Please note that it is important to confirm the capacitor polarity in the application.

## Application Descriptions

### Effective Bypass Capacitor, C<sub>bypass</sub>

As with any power amplifier, proper supply bypassing is critical for low noise performance and high power supply rejection.

The capacitor location on both the bypass and power supply pins should be as close to the device as possible. The effect of a larger half supply bypass capacitor is improved PSRR due to increased half-supply stability. Typical applications employ a 5V regulator with 1.0μF and a 0.1μF bypass capacitors which aid in supply filtering. This does not eliminate the need for bypassing the supply nodes of the APA2035. The selection of bypass capacitors, especially C<sub>b</sub>, is thus dependent upon desired PSRR requirements, click and pop performance.

To avoid start-up pop noise occurred, the bypass voltage should be rise slower then the input bias voltage and the relationship shown in equation should be maintained.

$$\frac{1}{C_{bypass} \times 160k\Omega} \ll \frac{1}{C_i \times R_i} \quad (4)$$

The capacitor is fed from a 125kΩ source inside the amplifier. Bypass capacitor, C<sub>b</sub>, values of 3.3μF to 10μF ceramic or tantalum low-ESR capacitors are recommended for the best THD and noise performance.

The bypass capacitance also effect to the start up time. It is determined in the follow equation:

$$T_{start\ up} = 5 \times (C_{bypass} \times 125k\Omega) \quad (5)$$

### Output Coupling Capacitor, C<sub>c</sub>

In the typical single-supply SE configuration, an output coupling capacitor (C<sub>c</sub>) is required to block the DC bias at the output of the amplifier thus preventing DC currents in the load. As with the input coupling capacitor, the output coupling capacitor and impedance of the load form a high-pass filter governed by equation.

$$f_c(\text{highpass}) = \frac{1}{2\pi R_L C_c} \quad (6)$$

For example, a 330μF capacitor with an 8Ω speaker would attenuate low frequencies below 60.6Hz. The main disadvantage, from a performance standpoint, is the load impedance is typically small, which drives the low-frequency corner higher degrading the bass response. Large values of C<sub>c</sub> are required to pass low frequencies into the load.

### Power Supply Decoupling, C<sub>s</sub>

The APA2035 is a high-performance CMOS audio amplifier that requires adequate power supply decoupling to ensure the output total harmonic distortion (THD) is as low as possible.

Power supply decoupling also prevents the oscillations causing by long lead length between the amplifier and the speaker.

The optimum decoupling is achieved by using two different type capacitors that target on different type of noise on the power supply leads. For higher frequency transients, spikes, or digital hash on the line, a good low equivalent-series-resistance(ESR) ceramic capacitor, typically 0.1μF placed as close as possible to the device V<sub>DD</sub> lead works best. For filtering lower-frequency noise signals, a large aluminum electrolytic capacitor of 10μF or greater placed near the audio power amplifier is recommended.

### Shutdown Function

In order to reduce power consumption while not in use, the APA2035 contains a shutdown pin to externally turn off the amplifier bias circuitry. This shutdown feature turns the amplifier off when a logic low is placed on the SHUTDOWN pin. The trigger point between a logic high and logic low level is typically 2.0V. It is best to switch between ground and the supply V<sub>DD</sub> to

## Application Descriptions

### Shutdown Function (Cont.)

provide maximum device performance. switching the SHUTDOWN pin to low, the amplifier enters a low-current state,  $I_{DD} < 50\mu A$ . APA2035 is in shutdown mode, except PC-BEEP detect circuit. On normal operating, SHUTDOWN pin pull to high level to keeping the IC out of the shutdown mode. The SHUTDOWN pin should be tied to a definite voltage to avoid unwanted state changes.

### PC-BEEP Detection

APA2035 integrates a PCBEEP detect circuit for NOTEBOOK PC used. When PC-BEEP signal drive to PCBEEP input pin, and PCBEEP mode is active. APA2035 will force to BTL mode and the internal gain fixed as -10dB. The PCBEEP signal becomes the amplifier input signal and play on the speaker without coupling capacitor. If the amplifier in the shutdown mode, it will out of shutdown mode whenever PCBEEP mode enable. The APA2035 will return to previous setting when it is out of PC-BEEP mode.

The input impedance is 100kΩ on PCBEEP input pin.

### Optimizing Depop Circuitry

Circuitry has been included in the APA2035 to minimize the amount of popping noise at power-up and when coming out of shutdown mode. Popping occurs whenever a voltage step is applied to the speaker. In order to eliminate clicks and pops, all capacitors must be fully discharged before turn-on. Rapid on/off switching of the device or the shutdown function will cause the click and pop circuitry. The value of  $C_i$  will also affect turn-on pops. (Refer to Effective Bypass Capacitance) The bypass voltage rise up should be slower than input bias voltage. Although the bypass pin current source cannot be modified, the size of  $C_b$  can be changed to alter the device turn-on time and the amount of clicks and pops. By increasing the value

of  $C_b$ , turn-on pop can be reduced. However, the tradeoff for using a larger bypass capacitor is to increase the turn-on time for this device. There is a linear relationship between the size of  $C_b$  and the turn-on time.

In a SE configuration, the output coupling capacitor,  $C_c$ , is of particular concern. This capacitor discharges through the internal 10kΩ resistors. Depending on the size of  $C_c$ , the time constant can be relatively large. To reduce transients in SE mode, an external 1kΩ resistor can be placed in parallel with the internal 10kΩ resistor. The tradeoff for using this resistor is an increase in quiescent current.

In the most cases, choosing a small value of  $C_i$  in the range of 0.33μF to 1μF,  $C_b$  being equal to 0.47μF and an external 1kΩ resistor should be placed in parallel with the internal 10kΩ resistor should produce a virtually clickless and popless turn-on.

A high gain amplifier intensifies the problem as the small delta in voltage is multiplied by the gain. So it is advantageous to use low-gain configurations.

### BTL Amplifier Efficiency

An easy-to-use equation to calculate efficiency starts out as being equal to the ratio of power from the power supply to the power delivered to the load. The following equations are the basis for calculating amplifier efficiency.

$$\text{Efficiency} = \frac{P_o}{P_{SUP}} \tag{7}$$

Where:

$$P_o = \frac{V_{rms} \times V_{rms}}{R_L} = \frac{V_P \times V_P}{2R_L} \tag{8}$$

$$V_{o\ rms} = \frac{V_P}{\sqrt{2}}$$

$$P_{sup} = V_{DD} * I_{DD\ AVG} = \frac{2V_P}{\pi R_L}$$

## Application Descriptions

### BTL Amplifier Efficiency (Cont.)

Efficiency of a BTL configuration:

$$\frac{P_o}{P_{SUP}} = \left( \frac{V_P \times V_P}{2R_L} \right) / \left( V_{DD} \times \frac{2V_P}{\pi R_L} \right) = \frac{\pi V_P}{4V_{DD}} \quad (9)$$

Table 2 calculates efficiencies for four different output power levels. Note that the efficiency of the amplifier is quite low for lower power levels and rises sharply as power to the load is increased resulting in a nearly flat internal power dissipation over the normal operating range. Note that the internal dissipation at full output power is less than in the half power range. Calculating the efficiency for a specific system is the key to proper power supply design. For a stereo 1W audio system with 8Ω loads and a 5V supply, the maximum draw on the power supply is almost 3W.

Po (W)	Efficiency (%)	I <sub>DD</sub> (A)	V <sub>PP</sub> (V)	P <sub>D</sub> (W)
0.25	31.25	0.16	2.00	0.55
0.50	47.62	0.21	2.83	0.55
1.00	66.67	0.30	4.00	0.5
1.25	78.13	0.32	4.47	0.35

\*\*High peak voltages cause the THD to increase.

Table 2. Efficiency Vs Output Power in 5V/8Ω BTL Systems

A final point to remember about linear amplifiers (either SE or BTL) is how to manipulate the terms in the efficiency equation to utmost advantage when possible. Note that in equation, V<sub>DD</sub> is in the dominator. This indicates that as V<sub>DD</sub> goes down, efficiency goes up. In other words, use the efficiency analysis to choose the correct supply voltage and speaker impedance for the application.

### Power Dissipation

Whether the power amplifier is operated in BTL or SE modes, power dissipation is a major concern. In equa

tion10 states the maximum power dissipation point for a SE mode operating at a given supply voltage and driving a specified load.

$$\text{SE mode : } P_{D,MAX} = \frac{V_{DD}}{2\pi R_L} \quad (10)$$

In BTL mode operation, the output voltage swing is doubled as in SE mode. Thus the maximum power dissipation point for a BTL mode operating at the same given conditions is 4 times as in SE mode.

$$\text{BTL mode : } P_{D,MAX} = \frac{4V_{DD}^2}{2\pi R_L} \quad (11)$$

Since the APA2035 is a dual channel power amplifier, the maximum internal power dissipation is 2 times that both of equations depending on the mode of operation. Even with this substantial increase in power dissipation, the APA2035 does not require extra heatsink. The power dissipation from equation11, assuming a 5V-power supply and an 8Ω load, must not be greater than the power dissipation that results from the equation13:

$$P_{D,MAX} = \frac{T_{J,MAX} - T_A}{\theta_{JA}} \quad (12)$$

For TSSOP-24 package with and without thermal pad, the thermal resistance (θ<sub>JA</sub>) is equal to 45°C/W.

Since the maximum junction temperature (T<sub>J,MAX</sub>) of APA2035 is 150°C and the ambient temperature (T<sub>A</sub>) is defined by the power system design, the maximum power dissipation which the IC package is able to handle can be obtained from equation12. Once the power dissipation is greater than the maximum limit (P<sub>D,MAX</sub>), either the supply voltage (V<sub>DD</sub>) must be decreased, the load impedance (R<sub>L</sub>) must be increased or the ambient temperature should be reduced.

### Thermal Pad Considerations

The thermal pad must be connected to ground. The

## Application Descriptions

### Thermal Pad Considerations (Cont.)

package with thermal pad of the APA2035 requires special attention on thermal design. If the thermal design issues are not properly addressed, the APA2035 4Ω will go into thermal shutdown when driving a 4Ω load.

The thermal pad on the bottom of the APA2035 should be soldered down to a copper pad on the circuit board. Heat can be conducted away from the thermal pad through the copper plane to ambient. If the copper plane is not on the top surface of the circuit board, 8 to 10 vias of 13 mil or smaller in diameter should be used to thermally couple the thermal pad to the bottom plane. For good thermal conduction, the vias must be plated through and solder filled. The copper plane used to conduct heat away from the thermal pad should be as large as practical.

If the ambient temperature is higher than 25°C, a larger copper plane or forced-air cooling will be required to keep the APA2035 junction temperature below the thermal shutdown temperature (150°C).

In higher ambient temperature, higher airflow rate and/or larger copper area will be required to keep the IC out of thermal shutdown.

### Thermal Considerations

Linear power amplifiers dissipate a significant amount of heat in the package under normal operating conditions.

To calculate maximum ambient temperatures, first consideration is that the numbers from the **Power Dissipation vs. Output Power** graphs (page15) are per channel values, so the dissipation of the IC heat needs to be doubled for two-channel operation. Given  $\theta_{JA}$ , the maximum allowable junction temperature ( $T_{J,MAX}$ ), and the total internal dissipation ( $P_D$ ), the maximum ambient temperature can be calculated with

the following equation. The maximum recommended junction temperature for the APA2035 is 150°C. The internal dissipation figures are taken from the **Power Dissipation vs. Output Power** graphs (Page15).

$$T_{A,Max} = T_{J,Max} - \theta_{JA} P_D \quad (13)$$

$$150 - 45(0.8*2) = 78^\circ\text{C (TSSOP-P24)}$$

The APA2035 is designed with a thermal shutdown protection that turns the device off when the junction temperature surpasses 150°C to prevent damaging the IC.

## Physical Specifications

Terminal Material	Solder-Plated Copper (Solder Material : 90/10 or 63/37 SnPb), 100%Sn
Lead Solderability	Meets EIA Specification RSI86-91, ANSI/J-STD-002 Category 3.

### Reflow Condition (IR/Convection or VPR Reflow)

### Classification Reflow Profiles

Profile Feature	Sn-Pb Eutectic Assembly	Pb-Free Assembly
Average ramp-up rate (T <sub>L</sub> to T <sub>P</sub> )	3°C/second max.	3°C/second max.
Preheat		
- Temperature Min (T <sub>smin</sub> )	100°C	150°C
- Temperature Max (T <sub>smax</sub> )	150°C	200°C
- Time (min to max) (t <sub>s</sub> )	60-120 seconds	60-180 seconds
Time maintained above:		
- Temperature (T <sub>L</sub> )	183°C	217°C
- Time (t <sub>L</sub> )	60-150 seconds	60-150 seconds
Peak/Classification Temperature (T <sub>p</sub> )	See table 1	See table 2
Time within 5°C of actual Peak Temperature (t <sub>p</sub> )	10-30 seconds	20-40 seconds
Ramp-down Rate	6°C/second max.	6°C/second max.
Time 25°C to Peak Temperature	6 minutes max.	8 minutes max.

Notes: All temperatures refer to topside of the package .Measured on the body surface.

## Classification Reflow Profiles (Cont.)

Table 1. SnPb Eutectic Process – Package Peak Reflow Temperatures

Package Thickness	Volume mm <sup>3</sup> <350	Volume mm <sup>3</sup> ≥350
<2.5 mm	240 +0/-5°C	225 +0/-5°C
≥2.5 mm	225 +0/-5°C	225 +0/-5°C

Table 2. Pb-free Process – Package Classification Reflow Temperatures

Package Thickness	Volume mm <sup>3</sup> <350	Volume mm <sup>3</sup> 350-2000	Volume mm <sup>3</sup> >2000
<1.6 mm	260 +0°C*	260 +0°C*	260 +0°C*
1.6 mm – 2.5 mm	260 +0°C*	250 +0°C*	245 +0°C*
≥2.5 mm	250 +0°C*	245 +0°C*	245 +0°C*

\*Tolerance: The device manufacturer/supplier **shall** assure process compatibility up to and including the stated classification temperature (this means Peak reflow temperature +0°C. For example 260°C+0°C) at the rated MSL level.

## Reliability Test Program

Test item	Method	Description
SOLDERABILITY	MIL-STD-883D-2003	245°C, 5 SEC
HOLT	MIL-STD-883D-1005.7	1000 Hrs Bias @125°C
PCT	JESD-22-B,A102	168 Hrs, 100%RH, 121°C
TST	MIL-STD-883D-1011.9	-65°C~150°C, 200 Cycles
ESD	MIL-STD-883D-3015.7	VHBM > 2KV, VMM > 200V
Latch-Up	JESD 78	10ms, 1 <sub>tr</sub> > 100mA
