Am78/8831·Am78/8832

Three-State Line Driver

Distinctive Characteristics

- Three-State Line Drivers pin-for-pin equivalent to the DM78/8831 and DM78/8832
- Mode control for quad single-ended or dual differential operation
- Common bus operation
- High-drive capability

- 40mA sink and source current
- Series 54/74 compatible
- 13ns typical propagation delay
- 100% reliability assurance testing in compliance with MIL-STD-883

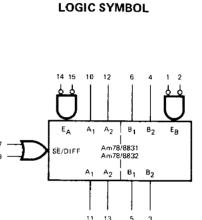

FUNCTIONAL DESCRIPTION

The Am78/8831 and Am78/8832 line drivers can be used either as a quad single-ended driver or as a dual differential driver. Each driver has a three-state output making the device particularly suitable for party-line operation where several drivers are directly connected to the same bus. The Am78/8832 does not have the V_{CC} clamp diodes found on the Am74/8831.

When used for single-ended operation the two differential/single-ended control inputs are held LOW. The device then operates as four independent non-inverting drivers. For differential working at least one differential/single-ended control input is held HIGH. The A-channel inputs are connected together and the B-channel inputs are connected together. Signal inputs will then pass non-inverted to the A2 and B2 outputs and inverted on the A4 and B4 outputs.

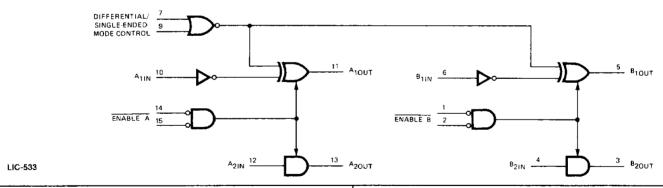

For party-line operation outputs of different channels are tied together, and outputs of all channels except one are forced into the third high impedance state by having at least one of the channel disable inputs HIGH. The channel that is enabled has both channel disable inputs LOW, and the low-output impedance of this output at both logic levels controls the level of the bus, provides good capacitance drive and insures good waveform integrity.

The channel which is enabled can conveniently be selected by a decoding matrix using Am9301 1-of-10 or Am9311 1-of-16 active LOW output decoders. The high drive capability at both logic levels enables drivers to drive a low impedance line and still supply the inverse leakage current of several disabled drivers.
