### 3.3V 256K $\times$ 32/36 pipelined burst synchronous SRAM

## Features

- Organization: 262,144 words x 32 or 36 bits
- Fast clock speeds to 166 MHz
- Fast clock to data access: $3.5 / 4.0 \mathrm{~ns}$
- Fast $\overline{\mathrm{OE}}$ access time: $3.5 / 4.0 \mathrm{~ns}$
- Fully synchronous register-to-register operation
- Single-cycle deselect
- Asynchronous output enable control
- Available in100-pin TQFP
- Individual byte write and global write
- Multiple chip enables for easy expansion
- 3.3 V core power supply
- 2.5 V or $3.3 \mathrm{~V} \mathrm{I/O}$ operation with separate $\mathrm{V}_{\mathrm{DDQ}}$
- Linear or interleaved burst control
- Snooze mode for reduced power-standby
- Common data inputs and data outputs
- 30 mW typical standby power in power down mode

## Functional description

The AS7C33256PFS32A and AS7C33256PFS36A are high-performance CMOS 8-Mbit Synchronous Static Random Access Memory (SRAM) devices organized as 262,144 words x 32 or 36 bits, and incorporate a two-stage register-register pipeline for highest frequency on any given technology.

Fast cycle times of $6 / 7.5 \mathrm{~ns}$ with clock access times ( $\mathrm{t}_{\mathrm{CD}}$ ) of $3.5 / 4.0 \mathrm{~ns}$ enable 166 and 133 MHz bus frequencies. Two-chip enable and three-chip enable ( $\overline{\mathrm{CE}}$ ) inputs permit versatility and easy memory expansion. Burst operation is initiated in one of two ways: the controller address strobe ( $\overline{\mathrm{ADSC}}$ ), or the processor address strobe $(\overline{\mathrm{ADSP}})$. The burst advance pin $(\overline{\mathrm{ADV}})$ allows subsequent internally generated burst addresses.
Read cycles are initiated with $\overline{\mathrm{ADSP}}$ (regardless of $\overline{\mathrm{WE}}$ and $\overline{\mathrm{ADSC}}$ ) using the new external address clocked into the on-chip address register when $\overline{\mathrm{ADSP}}$ is sampled LOW, the chip enables are sampled active, and the output buffer is enabled with $\overline{\mathrm{OE}}$. In a read operation the data accessed by the current address, registered in the address registers by the positive edge of CLK, are carried to the data-out registers and driven on the output pins on the next positive edge of CLK. $\overline{\mathrm{ADV}}$ is ignored on the clock edge that samples $\overline{\mathrm{ADSP}}$ asserted, but is sampled on all subsequent clock edges. Address is incremented internally for the next access of the burst when $\overline{\mathrm{ADV}}$ is sampled LOW, and both address strobes are HIGH. Burst mode is selectable with the $\overline{\mathrm{LBO}}$ input. With $\overline{\mathrm{LBO}}$ unconnected or driven HIGH , burst operations use an interleaved count sequence. With $\overline{\mathrm{LBO}}$ driven LOW, the device uses a linear count sequence.
Write cycles are performed by disabling the output buffers with $\overline{\mathrm{OE}}$ and asserting a write command. A global write enable $\overline{\mathrm{GWE}}$ writes all $32 / 36$ bits regardless of the state of individual $\overline{\mathrm{BW}[\mathrm{a}: \mathrm{d}]}$ inputs. Alternately, when $\overline{\mathrm{GWE}}$ is HIGH , one or more bytes may be written by asserting $\overline{\mathrm{BWE}}$ and the appropriate individual byte $\overline{\mathrm{BWn}}$ signal(s).
$\overline{\mathrm{BWn}}$ is ignored on the clock edge that samples $\overline{\mathrm{ADSP}} \mathrm{LOW}$, but is sampled on all subsequent clock edges. Output buffers are disabled when $\overline{\mathrm{BWn}}$ is sampled LOW (regardless of $\overline{\mathrm{OE}}$ ). Data is clocked into the data input register when $\overline{\mathrm{BWn}}$ is sampled LOW. Address is incremented internally to the next burst address if $\overline{\mathrm{BWn}}$ and $\overline{\mathrm{ADV}}$ are sampled LOW. This device operates in single cycle deselect features during real cycle.
Read or write cycles may also be initiated with $\overline{\mathrm{ADSC}}$ instead of $\overline{\mathrm{ADSP}}$. The differences between cycles initiated with $\overline{\mathrm{ADSC}}$ and $\overline{\mathrm{ADSP}}$ are as follows:

- $\overline{\text { ADSP }}$ must be sampled HIGH when $\overline{\text { ADSC }}$ is sampled LOW to initiate a cycle with $\overline{\mathrm{ADSC}}$.
$\cdot \overline{\mathrm{WE}}$ signals are sampled on the clock edge that samples $\overline{\mathrm{ADSC}}$ LOW (and $\overline{\mathrm{ADSP}} \mathrm{HIGH}$ ).
- Master chip enable $\overline{\mathrm{CE} 0}$ blocks $\overline{\mathrm{ADSP}}$, but not $\overline{\mathrm{ADSC}}$.

AS7C33256PFS32A and AS7C33256PFS36A family operates from a core 3.3 V power supply. I/Os use a separate power supply that can operate at 2.5 V or 3.3 V . These devices are available in a 100 -pin $14 \times 20 \mathrm{~mm}$ TQFP package.

## Signal descriptions

| Signal | I/O | Properties | Description |
| :---: | :---: | :---: | :---: |
| CLK | I | CLOCK | Clock. All inputs except $\overline{\mathrm{OE}}, \mathrm{ZZ}, \overline{\mathrm{LBO}}$ are synchronous to this clock. |
| A, A0, A1 | I | SYNC | Address. Sampled when all chip enables are active and $\overline{\text { ADSC }}$ or $\overline{\overline{\text { ADSP}}}$ are asserted. |
| DQ[a,b,c,d] | I/O | SYNC | Data. Driven as output when the chip is enabled and $\overline{\mathrm{OE}}$ is active. |
| $\overline{\mathrm{CE}} 0$ | I | SYNC | Master chip enable. Sampled on clock edges when $\overline{\mathrm{ADSP}}$ or $\overline{\mathrm{ADSC}}$ is active. When $\overline{\mathrm{CE} 0}$ is inactive, $\overline{\mathrm{ADSP}}$ is blocked. Refer to the Synchronous Truth Table for more information. |
| CE1, $\overline{\mathrm{CE} 2}$ | I | SYNC | Synchronous chip enables. Active HIGH and active LOW, respectively. Sampled on clock edges when $\overline{\mathrm{ADSC}}$ is active or when $\overline{\mathrm{CE} 0}$ and $\overline{\mathrm{ADSP}}$ are active. |
| $\overline{\text { ADSP }}$ | I | SYNC | Address strobe processor. Asserted LOW to load a new bus address or to enter standby mode. |
| $\overline{\text { ADSC }}$ | I | SYNC | Address strobe controller. Asserted LOW to load a new address or to enter standby mode. |
| $\overline{\text { ADV }}$ | I | SYNC | Advance. Asserted LOW to continue burst read/write. |
| $\overline{\text { GWE }}$ | I | SYNC | Global write enable. Asserted LOW to write all $32 / 36$ bits. When HIGH, $\overline{\overline{B W E}}$ and $\overline{\mathrm{BW}}[\mathrm{a}: \mathrm{d}]$ control write enable. |
| $\overline{\text { BWE }}$ | I | SYNC | Byte write enable. Asserted LOW with $\overline{\mathrm{GWE}}=\mathrm{HIGH}$ to enable effect of $\overline{\mathrm{BW}[\mathrm{a}: \mathrm{d}]}$ inputs. |
| $\overline{\mathrm{BW}}[\mathrm{a}, \mathrm{b}, \mathrm{c}, \mathrm{d}]$ | I | SYNC | Write enables. Used to control write of individual bytes when $\overline{\mathrm{GWE}}=\mathrm{HIGH}$ and $\overline{\mathrm{BWE}}=$ LOW. If any of $\overline{\mathrm{BW}[\mathrm{a}: \mathrm{d}]}$ is active with $\overline{\mathrm{GWE}}=\mathrm{HIGH}$ and $\overline{\mathrm{BWE}}=$ LOW the cycle is a write cycle. If all $\overline{\mathrm{BW}[\mathrm{a}: \mathrm{d}]}$ are inactive the cycle is a read cycle. |
| $\overline{\mathrm{OE}}$ | I | ASYNC | Asynchronous output enable. I/O pins are driven when $\overline{\mathrm{OE}}$ is active and the chip is in read mode. |
| $\overline{\mathrm{LBO}}$ | I | STATIC | Selects Burst mode. When tied to $\mathrm{V}_{\mathrm{DD}}$ or left floating, device follows Interleaved Burst order. When driven Low, device follows linear Burst order. This signal is internally pulled High. |
| ZZ | I | ASYNC | Snooze. Places device in LOW power mode; data is retained. Connect to GND if unused. |
| NC | - | - | No connect |

## Snooze Mode

SNOOZE MODE is a low current, power-down mode in which the device is deselected and current is reduced to $\mathrm{I}_{\mathrm{SB} 2}$. The duration of SNOOZE MODE is dictated by the length of time the ZZ is in a High state.

The ZZ pin is an asynchronous, active high input that causes the device to enter SNOOZE MODE.
When the ZZ pin becomes a logic High, $\mathrm{I}_{\mathrm{SB} 2}$ is guaranteed after the time $\mathrm{t}_{\mathrm{ZZI}}$ is met. After entering SNOOZE MODE, all inputs except ZZ is disabled and all outputs go to High-Z. Any operation pending when entering SNOOZE MODE is not guaranteed to successfully complete. Therefore, SNOOZE MODE (READ or WRITE) must not be initiated until valid pending operations are completed. Similarly, when exiting SNOOZE MODE during $t_{\text {PUS }}$, only a DESELECT or READ cycle should be given while the SRAM is transitioning out of SNOOZE MODE.

$1 \mathrm{X}=$ don't care, $\mathrm{L}=$ low, $\mathrm{H}=$ high
2 For $\overline{\text { WRITE }}, L$ means any one or more byte write enable signals $(\overline{\mathrm{BWa}}, \overline{\mathrm{BWb}}, \overline{\mathrm{BWc}}$ or $\overline{\mathrm{BWd}})$ and $\overline{\mathrm{BWE}}$ are LOW or $\overline{\mathrm{GWE}}$ is LOW. $\overline{\text { WRITE }}=\mathrm{HIGH}$ for all $\overline{\mathrm{BWx}}, \overline{\mathrm{BWE}}, \overline{\mathrm{GWE}} \mathrm{HIGH}$. See "Write enable truth table (per byte)," on page 6 for more information.
3 For write operation following a READ, $\overline{\mathrm{OE}}$ must be high before the input data set up time and held high throughout the input hold time
4 ZZ pin is always Low.

## Key to switching waveforms

$\square$ Rising input $\quad \square$ don't care $\quad \square$ Unding input $\quad \square$ Undefined

Timing waveform of read cycle

Note: $\mathrm{Y}=\mathrm{XOR}$ when $\overline{\mathrm{LBO}}=$ high/no connect; $\mathrm{Y}=\mathrm{ADD}$ when $\overline{\mathrm{LBO}}=$ low. $\overline{\mathrm{BW}[\mathrm{a}: \mathrm{d}]}$ is don't care.

Timing waveform of write cycle

Note: $\mathrm{Y}=\mathrm{XOR}$ when $\overline{\mathrm{LBO}}=$ high/no connect; $\mathrm{Y}=\mathrm{ADD}$ when $\overline{\mathrm{LBO}}=$ low.

Timing waveform of read/write cycle ( $\overline{\text { ADSP }}$ Controlled; $\overline{\text { ADSC }}$ High)

Note: $\mathrm{Y}=\mathrm{XOR}$ when $\overline{\mathrm{LBO}}=$ high $/$ no connect $; \mathrm{Y}=\mathrm{ADD}$ when $\overline{\mathrm{LBO}}=$ low.

## AC test conditions

- Output load: see Figure B , except for $\mathrm{t}_{\mathrm{LZC}}, \mathrm{t}_{\mathrm{LZOE}}, \mathrm{t}_{\mathrm{HZOE}}, \mathrm{t}_{\mathrm{HZC}}$, see Figure C .
- Input pulse level: GND to 3V. See Figure A.
- Input rise and fall time (measured at 0.3 V and 2.7 V ): 2 ns . See Figure A.
- Input and output timing reference levels: 1.5 V .

Figure A: Input waveform

Figure B: Output load (A)

Figure C: Output load (B)

## Notes

1 For test conditions, see $A C$ Test Conditions, Figures A, B, and C.
2 This parameter measured with output load condition in Figure C.
3 This parameter is sampled, but not $100 \%$ tested.
$4 \mathrm{t}_{\mathrm{HZOE}}$ is less than $\mathrm{t}_{\text {LZOE }}$, and $\mathrm{t}_{\mathrm{HZC}}$ is less than $\mathrm{t}_{\mathrm{LZC}}$ at any given temperature and voltage.
5 tCH measured as high above $\mathrm{V}_{\mathrm{IH}}$, and tCL measured as low below $\mathrm{V}_{\mathrm{IL}}$.
6 This is a synchronous device. All addresses must meet the specified setup and hold times for all rising edges of CLK. All other synchronous inputs must meet the setup and hold times for all rising edges of CLK when chip is enabled.
7 Write refers to $\overline{\mathrm{GWE}}, \overline{\mathrm{BWE}}$, and $\overline{\mathrm{BW}[\mathrm{a}: \mathrm{d}]}$.
8 Chip select refers to $\overline{\mathrm{CE} 0}, \mathrm{CE} 1$, and $\overline{\mathrm{CE} 2}$.
