
#### Abstract

General Description The MAX15014-MAX15017 combine a step-down DCDC converter and a 50mA, low-quiescent-current lowdropout (LDO) regulator. The LDO regulator is ideal for powering always-on circuitry in automotive applications. The DC-DC converter input voltage range is 4.5 V to 40 V for the MAX15015/MAX15016, and 7.5 V to 40 V for the MAX15014/MAX15017 The DC-DC converter output is adjustable from 1.26 V to 32 V and can deliver up to 1A of load current. These devices utilize a feed-forward voltage-mode control scheme for good noise immunity in the high-voltage switching environment and offer external compensation allowing for maximum flexibility with a wide selection of inductor values and capacitor types. The switching frequency is internally fixed at 135 kHz and 500 kHz , depending on the version chosen. Moreover, the switching frequency can be synchronized to an external clock signal through the SYNC input. Light load efficiency is improved by automatically switching to a pulse-skip mode. The soft-start time is adjustable with an external capacitor. The DC-DC converter can be disabled independent of the LDO, thus reducing the quiescent current to $47 \mu \mathrm{~A}$ (typ). The LDO linear regulators operate from 5 V to 40 V and deliver a guaranteed 50mA load current. The devices feature a preset output voltage of 5V (MAX1501_A) or 3.3V (MAX1501_B). Alternatively, the output voltage can be adjusted from 1.5 V to 11 V by using an external resistive divider. The LDO section also features a RESET output with adjustable timeout period. Protection features include cycle-by-cycle current limit, hiccup-mode output short-circuit protection, and thermal shutdown. All devices are available in a space-saving, high-power (2.86W), 36-pin TQFN package and are rated for operation over the $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ automotive temperature range.

## Applications

Car Radios
Automotive Body Control Modules
Automotive Instrument Cluster
Navigation Systems

- Combined DC-DC Converters and Low-QuiescentCurrent LDO Regulators
- 1A DC-DC Converters Operate from 4.5V to 40V (MAX15015/MAX15016) or 7.5 V to 40V (MAX15014/MAX15017)
- Switching Frequency of $\mathbf{1 3 5 k H z}$ (MAX15014/MAX15016) or 500kHz (MAX15015/MAX15017)
- 50mA LDO Regulator Operates from 5V to 40V Independent of the DC-DC Converter
- 47 $\mu$ A Quiescent Current with DC-DC Converter Off and LDO On
- 6rA System Shutdown Current
- Frequency Synchronization Input
- Shutdown/Enable Inputs
- Adjustable Soft-Start Time
- Active-Low Open-Drain RESET Output with Programmable Timeout Delay
- Thermal Shutdown and Output Short-Circuit Protection
- Space-Saving ( $6 \mathrm{~mm} \times 6 \mathrm{~mm}$ ) Thermally Enhanced 36-Pin TQFN Package

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

| 34 | 34 | REG | Internal Regulator Output. 5V output for the MAX15015/MAX15016 and 8V output for the MAX15014/MAX15017. Bypass to SGND with at least a $1 \mu \mathrm{~F}$ ceramic capacitor. |
| 36 | 36 | IN_SW | Supply Input Connection. Connect to IN_LDO and an external voltage source from 4.5 V to 40V. EN_SW and EN_SYS must be high and IN_SW must be above its UVLO threshold for operation of the switching regulator. |
| - | - | EP | Exposed Pad. The exposed pad must be electrically connected to SGND. For an effective heatsinking, solder the exposed pad to a large copper plane. |

## 1A, 4.5V to 40V Input Buck Converters with 50mA Auxiliary LDO Regulators

Detailed Description
The MAX15014-MAX15017 combine a voltage-mode buck converter with an internal $0.5 \Omega$ power MOSFET switch and a low-quiescent-current LDO regulator. The buck converter of the MAX15015/MAX15016 has a wide input voltage range of 4.5 V to 40 V . The MAX15014/MAX15017's input voltage range is 7.5 V to 40 V . Fixed switching frequencies of 135 kHz and 500 kHz are available. The internal low RDS_ON switch allows for up to 1A of output current, and the output voltage can be adjusted from 1.26 V to 32 V . External compensation and voltage feed-forward simplify loop compensation design and allow for a wide variety of $L$ and C filter components. All devices offer an automatic switchover to pulse-skipping (PFM) mode, providing low quiescent current and high efficiency at light loads. Under no load, PFM mode operation reduces the current consumption to 5.6 mA for the MAX15014/ MAX15017 and 8.6mA for the MAX15015/MAX15016. In shutdown (DC-DC and LDO regulator off), the supply
current falls to $6 \mu \mathrm{~A}$. Additional features include a programmable soft-start, cycle-by-cycle current limit, hiccup-mode output short-circuit protection, and thermal shutdown.
The LDO linear regulator operates from 5 V to 40 V and delivers a guaranteed 50 mA load current. The devices feature a preset output voltage of 5.0V (MAX1501_A) or 3.3V (MAX1501_B). Alternatively, the output voltage can be adjusted from 1.5 V to 11 V using an external resistive divider. The LDO section also features a RESET output with adjustable timeout period.

Enable Inputs and UVLO The MAX15014-MAX15017 feature two logic inputs, EN_SW (active-high) and EN_SYS (active-high) that can be used to enable the switching power supply and the LDO_OUT outputs. When VEN_SW is higher than the threshold and EN_SYS is high, the switching power supply is enabled. When EN_SYS is high, the LDO is active. When EN_SYS is low, the entire chip is off (see Table 1).

Figure 1. MAX15015/MAX15016 Simplified Block Diagram

## 1A, 4.5V to 40V Input Buck Converters with 50mA Auxiliary LDO Regulators

Figure 2. MAX15014/MAX15017 Simplified Block Diagram
Table 1. Enable Inputs Configuration

| EN_SYS | EN_SW | LDO REGULATOR | DC-DC SWITCHING <br> CONVERTER |
| :---: | :---: | :---: | :---: |
| Low | Low | Off | Off |
| Low | High | Off | Off |
| High | Low | On | Off |
| High | High | On | On |

The MAX15014-MAX15017 provide undervoltage lockout (UVLO). The UVLO monitors the input voltage (VIN_LDO) and is fixed at 4.1V (MAX15015/MAX15016) or 7V (MAX15014/MAX15017).

Internal Linear Regulator (REG)
REG is the output terminal of a 5V (MAX15015/ MAX15016), or 8V (MAX15014/MAX15017) LDO which is powered from IN_SW and provides power to the IC.

Connect REG externally to DVREG to provide power for the high-side MOSFET gate driver. Bypass REG to SGND with a ceramic capacitor (CREG) of at least $1 \mu \mathrm{~F}$. Place the capacitor physically close to the MAX15014MAX15017 to provide good bypassing. During normal operation, REG is intended for powering up only the internal circuitry and should not be used to supply power to external loads.

# 1A, 4.5V to 40V Input Buck Converters with 50mA Auxiliary LDO Regulators 

## Soft-Start and Reference (SS)

SS is the 1.235 V reference bypass connection for the MAX15014-MAX15017 and also controls the soft-start period. At startup, after input voltage is applied at IN_SW, IN_LDO and the UVLO thresholds are reached, the device enters soft-start. During soft-start, $14 \mu \mathrm{~A}$ is sourced into the capacitor (Css) connected from SS to SGND causing the reference voltage to ramp up slowly. When Vss reaches 1.244 V , the output becomes fully active. Set the soft-start time (tss) using following equation:

$$
\mathrm{t}_{S S}=\frac{\mathrm{V}_{\mathrm{SS}} \times \mathrm{C}_{S S}}{I_{S S}}
$$

where VSS $=$ soft-start reference voltage $=1.235 \mathrm{~V}$ (typ), Iss $=$ soft-start current $=14 \times 10^{-6} \mathrm{~A}$ (typ), tss is in seconds and Css is in Farads.

## Internal Charge Pump <br> (MAX15015/MAX15016)

The MAX15015/MAX15016 feature an internal charge pump to enhance the turn-on of the internal MOSFET, allowing for operation with input voltages down to 4.5 V . Connect a flying capacitor (CF) between C+ and C-, a boost diode from C+ to BST, as well as a bootstrap capacitor (CBST) between BST and LX to provide the gate drive voltage for the high-side n-channel DMOS switch. During the on-time, the flying capacitor is charged to VDVREG. During the off-time, the positive terminal of the flying capacitor (C+) is pumped to two times VDVREG and charge is dumped onto CBST to provide twice the regulator voltage across the high-side DMOS driver. Use a ceramic capacitor of at least $0.1 \mu \mathrm{~F}$ for CbSt and CF located as close as possible to the device.

## Gate Drive Supply (DVREG)

DVREG is the supply input for the internal high-side MOSFET driver. The power for DVREG is derived from the output of the internal regulator (REG). Connect DVREG to REG externally. To filter the switching noise, the use of an RC filter ( $1 \Omega$ and $0.47 \mu \mathrm{~F}$ ) from REG to DVREG is recommended. In the MAX15015/MAX15016, the high-side drive supply is generated using the internal charge pump along with the bootstrap diode and capacitor. In the MAX15014/MAX15017, the high-side MOSFET driver supply is generated using only the bootstrap diode and capacitor.

## Error Amplifier

The output of the internal error amplifier (COMP) is available for frequency compensation (see the Compensation Design section). The inverting input is FB, the noninverting input SS, and the output COMP. The error amplifier has an

80 dB open-loop gain and a 1.8 MHz GBW product. See the Typical Operating Characteristics for the Gain and Phase vs. Frequency graph.

## Oscillator/Synchronization Input (SYNC)

 With SYNC connected to SGND, the MAX15014MAX15017 use their internal oscillator and switch at a fixed frequency of 135 kHz and 500 kHz . The MAX15014/ MAX15016 are the 135 kHz options and MAX15015/ MAX15017 are the 500 kHz options. For external synchronization, drive SYNC with an external clock from 400 kHz to 600 kHz (MAX15015/MAX15017) or 100 kHz to 200 kHz (MAX15014/MAX15016). When driven with an external clock, the device synchronizes to the rising edge of SYNC.
## PWM Comparator/Voltage Feed-Forward

 An internal ramp generator clocked by the internal oscillator is compared against the output of the error amplifier to generate the PWM signal. The maximum amplitude of the ramp (VRAMP) automatically adjusts to compensate for input voltage and oscillator frequency changes. This causes the VIN_SW / VRAMP to be a constant 10 V N across the input voltage range of 4.5 V to 40V (MAX15015/MAX15016) or 7.5 V to 40 V (MAX15014/ MAX15017) and the SYNC frequency range of 400 kHz to 600 kHz (MAX15015/MAX15017) or 100 kHz to 200 kHz (MAX15014/MAX15016).
## Output Short-Circuit Protection <br> (Hiccup Mode)

The MAX15014-MAX15017 protect against an output short circuit by utilizing hiccup-mode protection. In hiccup mode, a series of sequential cycle-by-cycle current-limit events cause the part to shut down and restart with a soft-start sequence. This allows the device to operate with a continuous output short circuit.
During normal operation, the current is monitored at the drain of the internal power MOSFET. When the current limit is exceeded, the internal power MOSFET turns off until the next on-cycle and a counter increments. If the counter counts seven consecutive current-limit events, the device discharges the soft-start capacitor and shuts down for 512 clock periods before restarting with a soft-start sequence. Each time the power MOSFET turns on and the device does not exceed the current limit, the counter is reset.

## LDO Regulator

The LDO regulator operates over an input voltage from 5 V to 40 V , and can be enabled independently of the DC-DC converter section. Its quiescent current is as low as $47 \mu \mathrm{~A}$ with a load current of $100 \mu \mathrm{~A}$. All devices

# 1A, 4.5V to 40V Input Buck Converters with 50mA Auxiliary LDO Regulators 

feature a preset output voltage of 5V (MAX1501_A) or 3.3V (MAX1501_B). Alternatively, the output voltage can be adjusted using an external resistive-divider network connected between LDO_OUT, SET_LDO, and SGND. See Figure 5.

#### Abstract

RESET Output The $\overline{\text { RESET }}$ output is typically connected to the reset input of a microprocessor ( $\mu \mathrm{P}$ ). A $\mu \mathrm{P}$ 's reset input starts or restarts the $\mu \mathrm{P}$ in a known state. The MAX15014MAX15017 supervisory circuits provide the reset logic to prevent code-execution errors during power-up, power-down, and brownout conditions. RESET changes from high to low whenever the monitored voltage drops below the $\overline{R E S E T}$ threshold voltage. Once the monitored voltage exceeds its respective RESET threshold voltage(s), $\overline{R E S E T}$ remains low for the RESET timeout period, then goes high. The RESET timeout period is adjustable with an external capacitor (CCT) connected to CT.

## Thermal-Shutdown Protection

The MAX15014-MAX15017 feature thermal shutdown protection which limits the total power dissipation in the device and protects it in the event of an extended thermal fault condition. When the die temperature exceeds $+160^{\circ} \mathrm{C}$, an internal thermal sensor shuts down the part, turning off the DC-DC converter and the LDO regulator, and allowing the IC to cool. After the die temperature falls by $20^{\circ} \mathrm{C}$, the part restarts with a soft-start sequence.

## Applications Information

## Setting the Output Voltage

Connect a resistive divider (R3 and R4, see Figures 6 and 7) from OUT to FB to SGND to set the output voltage. Choose R3 and R4 so that DC errors due to the FB input bias current do not affect the output-voltage setting precision. For the most common output-voltage settings ( 3.3 V or 5 V ), R3 values in the $10 \mathrm{k} \Omega$ range are adequate. Select R3 first and calculate R4 using the following equation:

$$
R 4=\frac{R 3}{\left[\frac{\mathrm{~V}_{\mathrm{OUT}}}{\mathrm{~V}_{\mathrm{FB}}}-1\right]}
$$

where V FB $=1.235 \mathrm{~V}$.

## Inductor Selection

Three key inductor parameters must be specified for operation with the MAX15014-MAX15017: inductance value (L), peak inductor current (IPEAK), and inductor saturation current (ISAT). The minimum required inductance is a function of operating frequency, input-to-output voltage differential, and the peak-to-peak inductor current ( $\Delta \mathrm{l} P-\mathrm{P}$ ). Higher $\Delta \mathrm{lP}-\mathrm{P}$ allows for a lower inductor value while a lower $\Delta l$ P-p requires a higher inductor value. A lower inductor value minimizes size and cost and improves large-signal and transient response, but reduces efficiency due to higher peak currents and higher peak-to-peak output voltage ripple for the same output capacitor. On the other hand, higher inductance increases efficiency by reducing the $\Delta l p-p$. Resistive losses due to extra wire turns can exceed the benefit gained from lower $\Delta$ lp-p levels especially when the inductance is increased without also allowing for larger inductor dimensions. A good compromise is to choose $\Delta$ lp-p equal to $40 \%$ of the full load current. Calculate the inductor using the following equation:

$$
L=\frac{V_{O U T}\left(V_{I N}-V_{O U T}\right)}{V_{\text {IN }} \times f_{S W} \times \Delta l_{P-P}}
$$

VIN and VOUT are typical values so that efficiency is optimum for typical conditions. The switching frequency (fSW) is internally fixed at 135 kHz (MAX15014/ MAX15016) or $500 \mathrm{kHz}($ MAX15015/MAX15017) and can vary when synchronized to an external clock (see the Oscillator/Synchronization Input (SYNC) section). The $\Delta l P-P$, which reflects the peak-to-peak output ripple, is worst at the maximum input voltage. See the Output-Capacitor Selection section to verify that the worst-case output ripple is acceptable. The inductor current (ISAT) is also important to avoid current runaway during continuous output short circuit. Select an inductor with an ISAT specification higher than the maximum peak current limit of 2.6A.

## Input-Capacitor Selection

The discontinuous input current of the buck converter causes large input ripple currents and therefore the input capacitor must be carefully chosen to keep the input voltage ripple within design requirements. The input voltage ripple is comprised of $\Delta \mathrm{V}_{\mathrm{Q}}$ (caused by the capacitor discharge) and $\Delta V_{E S R}$ (caused by the $E S R$ of the input capacitor). The total voltage ripple is the sum of $\Delta \mathrm{V}_{\mathrm{Q}}$ and $\Delta \mathrm{V}_{\mathrm{ESR}}$. Calculate the input capacitance and ESR required for a specified ripple using the following equations:

## 1A, 4.5V to 40V Input Buck Converters with 50mA Auxiliary LDO Regulators

$$
\begin{aligned}
& \mathrm{ESR}=\frac{\Delta \mathrm{V}_{\mathrm{ESR}}}{\mathrm{l}_{\mathrm{OUT}} \mathrm{MAX}+\frac{\Delta \mathrm{l}_{\mathrm{P}-\mathrm{P}}}{2}} \\
& \mathrm{C}_{\mathrm{IN}}=\frac{\mathrm{l}_{\mathrm{OUT}} \mathrm{MAX} \times \mathrm{D}}{\Delta \mathrm{~V}_{\mathrm{Q}} \times \mathrm{f}_{\mathrm{SW}}}
\end{aligned}
$$

where CIN is the sum of CDRAIN and additional decoupling capacitance at the buck converter input,

$$
\begin{aligned}
& \Delta l_{P-P}=\frac{\left(V_{I N}-V_{O U T}\right) \times V_{\text {OUT }}}{V_{I N} \times f_{S W} \times L} \text { and } \\
& D=\frac{V_{O U T}}{V_{I N}}
\end{aligned}
$$

IOUT_MAX is the maximum output current, $D$ is the duty cycle, and fsw is the switching frequency.
The MAX15014-MAX15017 include UVLO hysteresis and soft-start to avoid chattering during turn-on. However, use additional bulk capacitance if the input source impedance is high. Use enough input capacitance at lower input voltages to avoid possible undershoot below the undervoltage lockout threshold during transient loading.

## Output-Capacitor Selection

The allowable output voltage ripple and the maximum deviation of the output voltage during load steps determine the output capacitance (COUT) and its equivalent series resistance (ESR). The output ripple is mainly composed of $\Delta \mathrm{V}_{\mathrm{Q}}$ (caused by the capacitor discharge) and $\triangle \mathrm{V}$ ESR (caused by the voltage drop across the ESR of the output capacitor). The equations for calculating the peak-to-peak output voltage ripple are:

$$
\begin{aligned}
& \Delta V_{Q}=\frac{\Delta l_{P-P}}{8 \times C_{O U T} \times f_{S W}} \\
& \Delta V_{E S R}=E S R \times \Delta l_{P-P}
\end{aligned}
$$

Normally, a good approximation of the output voltage ripple is $\Delta \mathrm{V}_{\text {RIPPLE }}=\Delta \mathrm{V}_{\mathrm{ESR}}+\Delta \mathrm{V}_{\mathrm{Q}}$. If using ceramic capacitors, assume the contribution to the output voltage ripple from ESR and the capacitor discharge to be equal to 20\% and $80 \%$, respectively. $\Delta \mathrm{lP}$-p is the peak-to-peak inductor current (see the Input-Capacitor Selection section) and fsw is the converter's switching frequency.
The allowable deviation of the output voltage during fast load transients also determines the output capaci-
tance, its ESR, and its equivalent series inductance (ESL). The output capacitor supplies the load current during a load step until the controller responds with a greater duty cycle. The response time (tRESPONSE) depends on the closed-loop bandwidth of the converter (see the Compensation Design section). The resistive drop across the output capacitor's ESR, the drop across the capacitor's ESL ( $\Delta \mathrm{V}_{\mathrm{ESL}}$ ), and the capacitor discharge causes a voltage droop during the loadstep.
Use a combination of low-ESR tantalum/aluminum electrolytic and ceramic capacitors for better transient load and voltage ripple performance. Non-leaded capacitors and capacitors in parallel help reduce the ESL. Keep the maximum output voltage deviation below the tolerable limits of the electronics being powered. Use the following equations to calculate the required ESR, ESL, and capacitance value during a load step:

$$
\begin{aligned}
& \mathrm{ESR}=\frac{\Delta \mathrm{V}_{\mathrm{ESR}}}{I_{\mathrm{STEP}}} \\
& \mathrm{C}_{\mathrm{OUT}}=\frac{I_{\text {STEP }} \times t_{\text {RESPONSE }}}{\Delta \mathrm{V}_{\mathrm{Q}}} \\
& \mathrm{ESL}=\frac{\Delta \mathrm{V}_{\mathrm{ESL}} \times \mathrm{t}_{\text {STEP }}}{I_{\text {STEP }}} \\
& \mathrm{t}_{\text {RESPONSE }} \cong \frac{1}{3 f_{\mathrm{C}}}
\end{aligned}
$$

where ISTEP is the load step, tSTEP is the rise time of the load step, tRESPONSE is the response time of the controller and fc is the closed-loop crossover frequency.

## Compensation Design

The MAX15014-MAX15017 use a voltage-mode control scheme that regulates the output voltage by comparing the error amplifier output (COMP) with an internal ramp to produce the required duty cycle. The output lowpass LC filter creates a double pole at the resonant frequency, which has a gain drop of $-40 \mathrm{~dB} / \mathrm{decade}$. The error amplifier must compensate for this gain drop and phase shift to achieve a stable closed-loop system.
The basic regulator loop consists of a power modulator, an output feedback divider, and a voltage error amplifier. The power modulator has a DC gain set by VIN / VRAMP, with a double pole and a single zero set by the output inductance (L), the output capacitance (COUT), and its ESR. The power modulator incorporates a voltage feed-forward feature, which automatically adjusts for variations in the input voltage resulting in a DC gain of 10 .

## 1A, 4.5V to 40V Input Buck Converters with 50mA Auxiliary LDO Regulators

The following equations define the power modulator:

$$
\begin{aligned}
& G_{M O D} D C=\frac{V_{I N}}{V_{\text {RAMP }}}=10 \\
& \mathrm{f}_{\mathrm{LC}}=\frac{1}{2 \times \pi \times \sqrt{\text { L×C } C_{O U T}}} \\
& \mathrm{f}_{\mathrm{ZESR}}=\frac{1}{2 \times \pi \times \mathrm{C}_{\mathrm{OUT}} \times \mathrm{ESR}}
\end{aligned}
$$

The switching frequency is internally set at 500 kHz for MAX15015/MAX15017 and can vary from 400 kHz to 600 kHz when driven with an external SYNC signal. The switching frequency is internally set at 135 kHz for MAX15014/MAX15016 and can vary from 100 kHz to 200 kHz when driven with an external sync signal. The crossover frequency (fC), which is the frequency when the closed-loop gain is equal to unity, should be set to around $1 / 10$ of the switching frequency or below.
The crossover frequency occurs above the LC doublepole frequency, and the error amplifier must provide a gain and phase bump to compensate for the rapid gain and phase loss from the LC double pole, which exhibits little damping.
This is accomplished by utilizing a Type 3 compensator that introduces two zeroes and three poles into the control loop. The error amplifier has a low-frequency pole (fP1) near the origin so that tight voltage regulation at DC can be achieved.
The two zeroes are at:

$$
\mathrm{f}_{\mathrm{ZI}}=\frac{1}{2 \pi \times R 5 \times \mathrm{C7}}
$$

and

$$
\mathrm{f}_{\mathrm{Z} 2}=\frac{1}{2 \pi \times(\mathrm{R} 3+\mathrm{R} 6) \times \mathrm{C} 6}
$$

and the higher frequency poles are at:

$$
f_{P 2}=\frac{1}{2 \pi \times R 6 \times C 6}
$$

and

$$
\mathrm{f}_{\mathrm{P} 3}=\frac{1}{2 \pi \times \mathrm{R} 5 \times \frac{\mathrm{C} 7 \times \mathrm{C} 8}{\mathrm{C} 7+\mathrm{C} 8}}
$$

The compensation design primarily depends on the type of output capacitor. Ceramic capacitors exhibit very low ESR, and are well suited for high-switchingfrequency applications, but are limited in capacitance

Figure 3. Error Amplifier Compensation Circuit (Closed-Loop and Error-Amplifier Gain Plot) for Ceramic Capacitors
value and tend to be more expensive. Aluminum electrolytic capacitors have much larger ESR but can reach much larger capacitance values.

## Compensation when fc fZESR

This is usually the case when a ceramic capacitor is selected. In this case, fZESR occurs after fc. Figure 3 shows the error amplifier feedback as well as its gain response.
fZ 1 is set to 0.5 to $0.8 \times \mathrm{fLC}$ and $\mathrm{fZ2}$ is set to fLC to compensate for the gain and phase loss due to the double pole. To achieve a OdB crossover with $-20 \mathrm{~dB} / \mathrm{decade}$ slope, poles $\mathrm{f}_{\mathrm{P} 2}$ and fp3 are set above the crossover frequency fc.
The values for R3 and R4 are already determined in the Setting the Output Voltage section. The value of R3 is also used in the following calculations.
Since $\mathrm{fZ} 2<\mathrm{f} C<\mathrm{fP} 2$, then R3 >> R6, and R3 + R6 can be approximated as R3.
Now we can calculate C6 for zero fz2 :

$$
\mathrm{C} 6=\frac{1}{2 \pi \times \mathrm{f}_{\mathrm{LC}} \times \mathrm{R} 3}
$$

## 1A, 4.5V to 40V Input Buck Converters with 50mA Auxiliary LDO Regulators

fc occurs between fz2 and fp2. In this region, the compensator gain (GEA) at fc is due primarily to C 6 and R 5 . Therefore, $\mathrm{GEA}_{\mathrm{EA}}(\mathrm{fC})=2 \pi \times \mathrm{fC} \times \mathrm{C} 6 \times \mathrm{R} 5$ and the modulator gain at fc is:

$$
\mathrm{G}_{\text {MOD }}\left(\mathrm{f}_{\mathrm{C}}\right)=\frac{\mathrm{G}_{\text {MOD_DC }}}{\left(2 \pi \times \mathrm{f}_{\mathrm{C}}\right)^{2} \times \mathrm{L} \times \mathrm{C}_{\text {OUT }}}
$$

Since $G_{E A}(f \mathrm{f}) \times \mathrm{GmOD}_{\mathrm{MO}}(\mathrm{fc})=1, R 5$ is calculated by:

$$
\mathrm{R} 5=\frac{\mathrm{f}_{\mathrm{C}} \times \mathrm{L} \times \mathrm{C}_{\text {OUT }} \times 2 \pi}{\mathrm{C} 6 \times \mathrm{G}_{\text {MOD_DC }}}
$$

The frequency of $\mathrm{f}_{\mathrm{Z}} 1$ is set to $0.5 \times \mathrm{fLC}$ and now we can calculate C7:

$$
\mathrm{C} 7=\frac{1}{0.5 \times 2 \pi \times \mathrm{R} 5 \times \mathrm{FLC}}
$$

$\mathrm{fP2}$ is set at $1 / 2$ the switching frequency ( $\mathrm{f} s w$ ). R6 is then calculated by:

$$
\left.\mathrm{R} 6=\frac{1}{2 \pi \times \mathrm{C} 6 \times(0.5 \times \mathrm{f} W}\right)
$$

Note that if the crossover frequency has been chosen as $1 / 10$ of the switching frequency, then fp2 $=5 \times f \mathrm{c}$.
The purpose of $\mathrm{fp3}$ is to further attenuate the residual switching ripple at the COMP pin.
If the ESR zero (fZESR) occurs in a region between fc and fsw / 2, then fp3 can be used to cancel it. This way, the Bode plot of the loop gain plot will not flatten out soon after the OdB crossover, and will maintain its $-20 \mathrm{~dB} /$ decade slope up to $1 / 2$ of the switching frequency.
If the ESR zero well exceeds fsw/2 (or even fsw), fp3 should in any case be set high enough not to erode the phase margin at the crossover frequency. For example, it can be set between $5 \times \mathrm{fc}$ and $10 \times \mathrm{fc}$.
The value for C 8 is calculated from:

$$
\mathrm{C} 8=\frac{\mathrm{C} 7}{\left(2 \pi \times \mathrm{C} 7 \times \mathrm{R} 5 \times \mathrm{fP}_{3}-1\right)}
$$

Compensation when fc $\boldsymbol{>}$ fZESR
For larger ESR capacitors such as tantalum and aluminum electrolytic, fZESR can occur before fc. If fZESR $<\mathrm{fc}$, then fc occurs between fp2 and fp3. fZ1 and fZ2 remain the same as before however, fP 2 is now set equal to fZESR. The output capacitor's ESR zero

Figure 4. Error Amplifier Compensation Circuit (Closed-Loop and Error-Amplifier Gain Plot) for Higher ESR Output Capacitors
frequency is higher than flc but lower than the closedloop crossover frequency. The equations that define the error amplifier's poles and zeros ( $\mathrm{fz} 1, \mathrm{fz} 2, \mathrm{fp} 2$, and $\mathrm{fp}_{3}$ ) are the same as before. However, fp2 is now lower than the closed-loop crossover frequency. Figure 4 shows the error amplifier feedback as well as its gain response for circuits that use higher-ESR output capacitors (tantalum or aluminum electrolytic).
Again, starting from R3, calculate C6 for zero fz2:

$$
\mathrm{C} 6=\frac{1}{2 \pi \times \mathrm{LC} \times \mathrm{R} 3}
$$

and then place fP2 to cancel the ESR zero. R6 is calculated as:

$$
\mathrm{R} 6=\frac{\mathrm{C}_{\text {OUT }} \times \mathrm{ESR}}{\mathrm{C} 6}
$$

If the value obtained here for R6 is not considerably smaller than R3, then recalculate C6 using (R3 + R6) in place of R3. Then use the new value of C6 to obtain a better approximation for R6. The process can be further iterated, and convergence is ensured as long as fLC < fZESR.

## 1A, 4.5 V to 40 V Input Buck Converters with 50mA Auxiliary LDO Regulators

The error amplifier gain between fp2 and fP3 is approximately equal to R5 / (R6 II R3).
The ESR zero frequency fZESR might not be very much higher than the double-pole frequency flc, therefore the value of R5 can be calculated as:

$$
R 5=\frac{R 3 \times R 6}{R 3+R 6} \times \frac{f_{C}{ }^{2}}{G_{M O D \_D C} \times f_{L C}{ }^{2}}
$$

C7 can still be calculated as:

$$
\mathrm{C} 7=\frac{1}{0.5 \times 2 \pi \times R 5 \times \mathrm{LC}}
$$

$\mathrm{fP}_{\mathrm{f}}$ is set at 5 xfc . Therefore, C 8 is calculated as:

$$
\mathrm{C} 8=\frac{\mathrm{C} 7}{2 \pi \times \mathrm{C} 7 \times \mathrm{R} 5 \times \mathrm{fP}_{\mathrm{f}}-1}
$$

## Setting the LDO Linear Regulator Output Voltage

The MAX15014-MAX15017 LDO regulator features Dual Mode ${ }^{T M}$ operation: it can operate in either a preset voltage mode or an adjustable mode. In preset voltage mode, internal trimmed feedback resistors set the internal linear regulator to 3.3 V or 5 V (see the Selector Guide). Select preset voltage mode by connecting SET_LDO to ground. In adjustable mode, select an output voltage between 1.5 V and 11 V using two external resistors connected as a voltage-divider to SET_LDO (see Figure 5). Set the output voltage using the following equation:

$$
\mathrm{V}_{\mathrm{OUT}}=\mathrm{V}_{\mathrm{SET}} \mathrm{LDO}\left(1+\frac{\mathrm{R} 1}{\mathrm{R} 2}\right)
$$

where $\mathrm{V}_{\text {SET_LDO }}=1.241 \mathrm{~V}$ and the recommended value for R 2 is around $50 \mathrm{k} \Omega$.

## Setting the RESET Timeout Delay

The RESET timeout period is adjustable to accommodate a variety of $\mu \mathrm{P}$ applications. Adjust the RESET timeout period by connecting a capacitor (CCT) between CT and SGND.

$$
\mathrm{t}_{\mathrm{RP}}=\frac{\mathrm{C}_{\mathrm{CT}} \times \mathrm{V}_{\mathrm{CT}-\mathrm{TH}}}{\mathrm{I}_{\mathrm{CT}}-\mathrm{THQ}}
$$

where $\mathrm{V}_{\text {CT-TH }}=$ delay comparator threshold (rising) $=$ 1.241 V (typ), ICT-THQ = CT charge current $=2 \times 10^{-6} \mathrm{~A}$ (typ), tRP is in seconds and CCT is in Farads.

Dual Mode is a trademark of Maxim Integrated Products, Inc.

Figure 5. Setting the Output Voltage Using a Resistive Divider
Connect CT to LDO_OUT to select the internally fixed timeout period. ССт must be low-leakage-type capacitor. Ceramic capacitors are recommended; do not use capacitors lower than 200pF to avoid the influence of parasitic capacitances.

## Capacitor Selection and Regulator Stability

For stable operation over the full temperature range and with load currents up to 50 mA , use a $10 \mu \mathrm{~F}$ (min) output capacitor (CLDO_OUT) with a maximum ESR of $0.4 \Omega$. To reduce noise and improve load-transient response, stability, and power-supply rejection, use larger output capacitor values. Some ceramic dielectrics such as Z5U and Y5V exhibit very large capacitance and ESR variation with temperature and are not recommended. With X7R or X5R dielectrics, $15 \mu \mathrm{~F}$ should be sufficient for operation over their rated temperature range. For higherESR tantalum capacitors (up to $1 \Omega$ ), use $22 \mu \mathrm{~F}$ or more to maintain stability. To improve power-supply rejection and transient response use a minimum $0.1 \mu \mathrm{~F}$ capacitor between IN_LDO and SGND.

Power Dissipation The MAX15014-MAX15017 are available in a thermally enhanced package and can dissipate up to 2.86 W at $\mathrm{T}_{\mathrm{A}}=+70^{\circ} \mathrm{C}$. When the die temperature reaches $+160^{\circ} \mathrm{C}$, the part shuts down and is allowed to cool. After the die cools by $20^{\circ} \mathrm{C}$, the device restarts with a soft-start. The power dissipated in the device is the sum of the power dissipated in the LDO, power dissipated from supply current $\left(\mathrm{PQ}_{\mathrm{Q}}\right)$, transition losses due to switching the internal power MOSFET (PSW), and the

## 1A, 4.5V to 40V Input Buck Converters with 50mA Auxiliary LDO Regulators

Figure 6. MAX15015/MAX15016 Typical Application Circuit (4.5V to 40V Input Operation)
power dissipated due to the RMS current through the internal power MOSFET (PMOSFET). The total power dissipated in the package must be limited such that the junction temperature does not exceed its absolute maximum rating of $+150^{\circ} \mathrm{C}$ at maximum ambient temperature. Calculate the power lost in the MAX15014MAX15017 using the following equations:
The power loss through the switch:

$$
\begin{aligned}
& \text { PMOSFET }=\left(I_{\text {RMS_MOSFET }}\right)^{2} \times \mathrm{R}_{\mathrm{ON}} \\
& \mathrm{I}_{\text {RMS_MOSFET }}=\sqrt{\frac{D}{3} \times\left[\mathrm{I}^{2} \mathrm{PK}+\left(\mathrm{l}_{\mathrm{PK}} \times \mathrm{I}_{\mathrm{DC}}\right)+\mathrm{I}^{2} \mathrm{DC}\right]} \\
& \mathrm{I}_{\mathrm{PK}}=\mathrm{I}_{\mathrm{OUT}}+\frac{\Delta \mathrm{I}_{\mathrm{P}} \mathrm{P}}{2} \\
& \mathrm{I}_{\mathrm{DC}}=\mathrm{I}_{\mathrm{OUT}}-\frac{\Delta I_{\mathrm{P}} \mathrm{P}}{2} \\
& \mathrm{D}=\frac{\mathrm{V}_{\mathrm{OUT}}}{V_{I N}}
\end{aligned}
$$

RON is the on-resistance of the internal power MOSFET (see the Electrical Characteristics).
The power loss due to switching the internal MOSFET:

$$
P_{S W}=\frac{V_{\text {IN }} \times I_{\text {OUT }} \times\left(t_{\mathrm{R}}+t_{\mathrm{F}}\right) \times f_{S W}}{4}
$$

$t_{R}$ and $t_{F}$ are the rise and fall times of the internal power MOSFET measured at LX.

The power loss due to the switching supply current (ISW):

$$
P_{Q}=V_{I N \_S W} \times I_{S W}
$$

The power loss due to the LDO regulator:

$$
\text { PLDO =(VIN_LDo - VLDO_OUT }) \times \text { LDO_OUT }
$$

The total power dissipated in the device will be:
PTOTAL = PMOSFET + PSW + PQ + PLDO
